Conditional pmf and cdf for discrete RVs

 \blacktriangleright Recall definition of conditional probability for events E and F

$$P(E \mid F) = \frac{P(E \cap F)}{P(F)}$$

- Change in likelihoods when information is given, renormalization
- Define the conditional pmf of RV X given Y as (both RVs discrete)

$$p_{X|Y}(x | y) = P[X = x | Y = y] = \frac{P[X = x, Y = y]}{P[Y = y]}$$

• Can rewrite as
$$\Rightarrow p_{X|Y}(x \mid y) = \frac{P[X = x, Y = y]}{P[Y = y]} = \frac{p_{XY}(x, y)}{p_Y(y)}$$

- ▶ Pmf for random variable x, given parameter y ("Y not random anymore")
- Define conditional cdf as (a range of X conditional on a value of Y)

$$F_{X|Y}(x \mid y) = \mathsf{P}\left[X \le x \mid \frac{Y}{y} = y\right] = \sum_{z \le x} p_{X|Y}(z \mid y)$$

Example

Example

- Independent Bernoulli Y and Z, variable X = Y + Z
- Conditional pmf of X given Y? For X = 0, Y = 0

$$p_{X|Y}(X = 0 | Y = 0) = \frac{P[X = 0, Y = 0]}{P[Y = 0]} = \frac{(1 - p)^2}{1 - p} = 1 - p$$

Or, from joint and marginal pdfs (just a matter of definition)

$$p_{X|Y}(X = 0 \mid Y = 0) = \frac{p_{XY}(0,0)}{p_Y(0)} = \frac{(1-p)^2}{1-p} = 1-p$$

Can compute the rest analogously

$$p_{X|Y}(0|0) = (1-p), \quad p_{X|Y}(1|0) = p, \qquad p_{X|Y}(2|0) = 0$$

$$p_{X|Y}(0|1) = 0, \qquad p_{X|Y}(1|1) = 1-p, \quad p_{X|Y}(2|1) = p$$

Conditional pdf and cdf for continuous RVs

▶ Define conditional pdf of RV X given Y as (both RVs continuous)

$$f_{X|Y}(x \mid y) = \frac{f_{XY}(x, y)}{f_Y(y)}$$

- ► For motivation, define intervals $\Delta x = [x, x+dx]$ and $\Delta y = [y, y+dy]$
- Can approximate conditional probability $\mathsf{P}\left[X \in \Delta x \mid Y \in \Delta y\right]$ as

$$\mathsf{P}\left[X \in \Delta x \mid Y \in \Delta y\right] = \frac{\mathsf{P}\left[X \in \Delta x, Y \in \Delta y\right]}{\mathsf{P}\left[Y \in \Delta y\right]} \approx \frac{f_{XY}(x, y)dxdy}{f_Y(y)dy}$$

▶ From definition of conditional pdf it follows after simplifying terms

$$\mathsf{P}\left[X \in \Delta x \mid Y \in \Delta y\right] \approx f_{X|Y}(x \mid y) dx$$

Which is what we would expect of a density

• Conditional cdf defined as
$$\Rightarrow F_{X|Y}(x) = \int_{-\infty}^{x} f_{X|Y}(u \mid y) du$$

- Random message (RV) Y, transmit signal y (realization of Y)
- Received signal is x = y + z (z realization of random noise)
- Can model communication system as a relation between RVs

$$X = Y + Z$$

- ▶ Model communication noise as $Z \sim \mathcal{N}(0, \sigma^2)$ independent of Y
- Conditional pdf of X given Y. Use definition:

$$f_{X|Y}(x \mid y) = \frac{f_{XY}(x, y)}{f_Y(y)} = \frac{?}{f_Y(y)}$$

- Problem is we don't know $f_{XY}(x, y)$. Have to calculate
- Computing conditional probs. typically easier than computing joints

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

- If Y = y is given, then "Y not random anymore" (Dorothy's principle)
 ⇒ It still is random in reality, we are thinking of it as given
- If Y were not random, say Y = y with y given then ...

$$X = \mathbf{y} + Z$$

Cdf of X, now easily obtained

$$P[X \le x] = P[y + Z \le x] = P[Z \le x - y] = \int_{-\infty}^{x-y} p_Z(z) dz$$

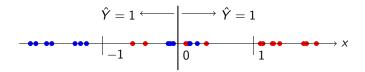

• But since Z is normal with 0 mean and variance σ^2

$$\mathsf{P}[X \le x] = \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{x-y} e^{-z^2/2\sigma^2} \, dz = \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{x} e^{-(z-y)^2/2\sigma^2} \, dz$$

• X is normal with mean y and variance σ^2

- Conditioning is a common tool to compute probabilities
- Message 1 (prob. p) \Rightarrow Transmit Y = 1 $Y = \pm 1$
- Message 2 (prob. q) \Rightarrow Transmit Y = -1
- Received signal $\Rightarrow X = Y + Z$
- Decoding rule $\Rightarrow \hat{Y} = 1$ if $X \ge 0$, $\hat{Y} = -1$ if X < 0
- What is the probability of error, $P_e := P\left[\hat{Y} \neq Y\right]$?
- Red dots to the left and blue dots to the right are errors

イロン 不聞 とくほとう ほどう

Output pdf

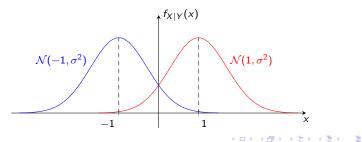

- ► From communications channel example we know
- If Y = 1, then $X \sim \mathcal{N}(1, \sigma^2)$, conditional pdf is

$$f_{X|Y}(x,1) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-1)^2/2\sigma^2}$$

▶ If Y = -1, then $X \sim \mathcal{N}(-1, \sigma^2)$, conditional pdf is

$$f_{X|Y}(x,-1) = \frac{1}{\sqrt{2\pi\sigma}} e^{-(x+1)^2/2\sigma^2}$$

Error probability

- ► Write probability of error by conditioning on $Y = \pm 1$ (total probability) $P_e = P\{\hat{Y} \neq Y \mid Y = 1\}P\{Y = 1\} + P\{\hat{Y} \neq Y \mid Y = -1\}P\{Y = -1\}$ $= P\{\hat{Y} = -1 \mid Y = 1\}p$ $+ P\{\hat{Y} = 1 \mid Y = -1\}q$
- But according to the decision rule

$$P_e = P\{X < 0 \mid Y = 1\}p + P\{X \ge 0 \mid Y = -1\}q$$

But X given Y is normally distributed, then

$$P_{e} = \frac{p}{\sqrt{2\pi\sigma}} \int_{0}^{\infty} e^{-(x-1)^{2}/2\sigma^{2}} + \frac{q}{\sqrt{2\pi\sigma}} \int_{-\infty}^{0} e^{-(x+1)^{2}/2\sigma^{2}} = \frac{1}{\sqrt{2\pi\sigma}} \int_{-\infty}^{-1} e^{-x^{2}/2\sigma^{2}}$$

$$N(-1, \sigma^{2}) \int_{-1}^{0} \int_{0}^{1} e^{-x^{2}/2\sigma^{2}} + \frac{q}{\sqrt{2\pi\sigma}} \int_{-\infty}^{0} e^{-(x+1)^{2}/2\sigma^{2}} = \frac{1}{\sqrt{2\pi\sigma}} \int_{-\infty}^{-1} e^{-x^{2}/2\sigma^{2}}$$
Analysis

Conditional probabilities

Conditional expectation

æ

► For continuous RVs X, Y define conditional expectation as

$$\mathbb{E}\left[X \mid y\right] = \int_{-\infty}^{\infty} x f_{X|Y}(x|y) \, dx$$

▶ For discrete RVs X, Y conditional expectation is

$$\mathbb{E}\left[X \mid y\right] = \sum_{x} x \, p_{X|Y}(x|y)$$

- Defined for given $y \Rightarrow \mathbb{E} [X | y]$ is a value
- All possible values y of $Y \Rightarrow$ random variable $\mathbb{E} \begin{bmatrix} X & Y \end{bmatrix}$
- Y is RV, $\mathbb{E}[X \mid y]$ value associated with outcome Y = y

・ロン ・四 と ・ ヨ と ・ 日 と

Double expectation

- If $\mathbb{E}[X \mid Y]$ is a RV, can compute expected value $\mathbb{E}_{Y}[\mathbb{E}_{X}(X \mid Y)]$
 - Subindices are for clarity purposes, innermost expectation is with respect to X, outermost with respect to Y
- What is $\mathbb{E}_{Y} [\mathbb{E}_{X} (X \mid Y)]$? Not surprisingly $\Rightarrow \mathbb{E} [X] = \mathbb{E}_{Y} [\mathbb{E}_{X} (X \mid Y)]$
- Show for discrete RVs (write integrals for continuous)

$$\mathbb{E}_{Y} \left[\mathbb{E}_{X} \left(X \mid Y \right) \right] = \sum_{y} \mathbb{E}_{X} \left(X \mid y \right) p_{Y}(y) = \sum_{y} \left[\sum_{x} x p_{X|Y}(x|y) \right] p_{Y}(y)$$
$$= \sum_{x} x \left[\sum_{y} p_{X|Y}(x|y) p_{Y}(y) \right] = \sum_{x} x \left[\sum_{y} p_{X,Y}(x,y) \right]$$
$$= \sum_{x} x p_{X}(x) = \mathbb{E} \left[X \right]$$

- Yields a method to compute expected values

 - $\begin{array}{ll}\Rightarrow \text{ Condition on } Y = y & \Rightarrow X \mid y \\ \Rightarrow \text{ Compute expected value over } X \text{ for given } y & \Rightarrow \mathbb{E}_X(X \mid y) \end{array}$
 - \Rightarrow Compute expected value over all values y of $Y \Rightarrow \mathbb{E}_{Y}[\mathbb{E}_{X}(X | Y)]$

Example

- Seniors get A = 4 with prob. 0.5, B = 3 with prob. 0.5
- ▶ Juniors get B = 3 with prob. 0.6, B = 2 with prob. 0.4
- ▶ Exchange student's standing: senior (junior) with prob. 0.7 (0.3)
- Expectation of X = exchange student's grade?
- Begin conditioning on standing

$$\mathbb{E} \left[X \mid \text{Senior} \right] = 0.5 \times 4 + 0.5 \times 3 = 3.5$$
$$\mathbb{E} \left[X \mid \text{Junior} \right] = 0.6 \times 3 + 0.4 \times 2 = 2.6$$

Now sum over standing's probability

$$\mathbb{E}[X] = \mathbb{E}[X | \text{Senior}] P[\text{Senior}] + \mathbb{E}[X | \text{Junior}] P[\text{Junior}]$$
$$= 3.5 \times 0.7 + 2.6 \times 0.3$$
$$= 3.23$$

► As with probabilities conditioning is useful to compute expectations.

 \Rightarrow Spreads difficulty into simpler problems

Example

- ► A baseball player hits X_i runs per game
- Expected number of runs is $\mathbb{E}[X_i] = \mathbb{E}[X]$ independently of game
- ▶ Player plays *N* games in the season. *N* is random (playoffs, injuries?)
- Expected value of number of games is $\mathbb{E}[N]$
- What is the expected number of runs in the season ? =

$$\Rightarrow \mathbb{E}\bigg[\sum_{i=1}^N X_i\bigg]$$

(日) (同) (日) (日) (日)

Both, N and X_i are random

Sum of random number of random quantities

Step 1: Condition on N = n then

$$\left[\left(\sum_{i=1}^{N} X_{i}\right) \mid N = n\right] = \sum_{i=1}^{n} X_{i}$$

Step 2: Compute expected value with respect to X_i

$$\mathbb{E}_{X_i}\left[\left(\sum_{i=1}^N X_i\right) \mid N=n\right] = \mathbb{E}\left[\sum_{i=1}^n X_i\right] = n\mathbb{E}\left[X\right]$$

Second equality possible because n is a number (not a RV like N) **Step 3:** Conpute expected value with respect to values n of N

$$\mathbb{E}_{N}\left[\mathbb{E}_{X_{i}}\left[\left(\sum_{i=1}^{N}X_{i}\right)\mid N\right]\right]=\mathbb{E}_{N}\left[N\mathbb{E}\left[X\right]\right]=\mathbb{E}\left[N\right]\mathbb{E}\left[X\right]$$

$$\mathsf{Yielding result} \ \Rightarrow \mathbb{E}\bigg[\sum_{i=1}^{N} X_i\bigg] = \mathbb{E}\left[N\right]\mathbb{E}\left[X\right]$$
