ESE535:
Electronic Design Automation

Day 13: March 3, 2015
Routing 1

Today
- Routing Cases
- Routing Problem
- Decomposition
- Channel Routing
- Variations
  - Over-the-cell

Routing Problem
Once know where blocks live (placement),
• How do we connect them up?
  – i.e. where do the wires go?
• In such a way as to:
  – Fit in fixed resources
  – Minimize resource requirements
    – (channel width $\rightarrow$ area)

Routing Cases
Gate Array
Standard Cell
Full Custom

Gate Array
- Fixed Grid
- Fixed row and column width
- Must fit into prefab channel capacity
- Resource-constrained routing

What freedom can we exploit in routing?
Gate Array

- Opportunities
  - Choice in paths
  - Exploit freedom to:
    - Meet channel limits
    - Minimize channel width

Gate Array

- What other paths could the red wire take?

Semicustom Array

- Float channel widths as needed
- How do we optimize area in this case?

Semicustom Array

- Float Channel widths as needed
- Area
  - minimize total channel widths
  \[ A = H \cdot V \]
  \[ H = \sum H_i \]
  \[ V = \sum V_i \]
Row-based Standard Cell

- Variable size
  - Cells
  - Channels
- Primary route within row
  - Minimize tracks in channel
- Vertical feed throughs

Standard Cell Gates

- IOs on one or both sides
- Design in Feed-thru

Full Custom / Macroblock

- Allow arbitrary geometry
  - Place larger cells
    - E.g. memory
  - Datapath blocks
- Less regular, but still have channels...

Routing Decomposed

Phased Routing

After placement...
1. Slice (macroblock case)
   - And order channels
2. Global Route
   - Which channels to use
     - (suitable approach Monday after break)
3. Channel Route
   - Today
4. Switchbox Route

Macroblock → Channel Route

- Slice into pieces
- Route each as channel
- Significance of numbers?
Macroblock → Channel Route

- **Slice** into pieces
- Route each as channel
- If work inside out
  - Can expand channels as needed
  - Complete in one pass

Not all Assemblies Sliceable

- No horizontal or vertical slice will separate
- Prevents ordering that allows us to route in one pass

Switchbox Routing

- Box with 3 or 4 sides fixed
- Contrast channel routing with only 2 sides fixed

Gate Array → Channel

- Global route first
  - Decide which path each signal takes
  - Sequence of channels
  - Minimize congestion
    - Wires per channel segment

Gate Array → Channel

- Then Channel route each resulting channel

Std.Cell → Channel Route

- Plan feed through
- Channel route each row
Channel Routing

- Key subproblem in all variants
- Pseudo 1D problem
- Given: set of terminals on one or both sides of channel
- Assign to tracks to minimize channel width

Channel Abstraction

Switchbox Route

- Terminals on 4 sides
- Link up terminal

Trivial Channel Routing

- Assign every net its own track
  - Channel width > N (single output functions)
  - Chip bisection $\propto N \Rightarrow \text{chip area } N^2$
Trivial Channel Routing

- How can we do better?
  - What do we want to exploit?

Sharing Tracks

- Want to Minimize tracks used
- Trick is to share tracks

Not that Easy

- With Two sides
  - Even assigning one track/signal may not be sufficient

Valid assignment avoids overlap

i.e. there are vertical constraints on ordering
Vertical Constraints

- For vertically aligned pins:
  - With single “vertical” routing layer
  - Cannot have distinct top pins on a lower track than bottom pins
  - Leads to vertical overlap
  - Produces constraint that top wire be higher track than lower
  - Combine across all top/bottom pairs
    - Leads to a Vertical Constraint Graph (VCG)

VCG Example

Channel Routing Complexity

- With Vertical Constraints
  - Problem becomes NP-complete
- Without Vertical Constraints
  - Can be solved optimally
  - Tracks = maximum channel density
  - Greedy algorithm

No Vertical Constraints

- Good for:
  - Single-sided channel
    - (no top and bottom pins)
  - Three layers for routing
    - Two vertical channels allow top and bottom pins to cross
    - May not be best way to use 3 layers...

Left-Edge Algorithm

1. Sort nets on leftmost end position
2. Start next lowest track; end=0
3. While there are unrouted nets with lowest left position > end of this track
   - Select unrouted net with lowest left position > end
   - Place selected net on this track
   - Update end position on this track to be end position of selected net
4. If nets remain, return to step 2

Example: Left-Edge

- Top: a b g b c d f
- Bottom: g d f e a c e
- Nets:
  - a: 1—5
  - b: 2—4
  - c: 5—6
  - d: 2—6
  - e: 4—7
  - f: 3—7
  - g: 1—3

Note: nets (shown as letters here) show up as numbers in conv. channel routing file formats.
Example: Left-Edge

- Top: a b g b c d f
- Bottom: g d f e a c

Nets:
- a:1—5
- b:2—4
- c:5—6
- d:2—6
- e:4—7
- f:3—7
- g:1—3

Sort Left Edge:
- a:1—5
- g:1—3
- b:2—4
- d:2—6
- f:3—7
- e:4—7
- c:5—6

Example: Left-Edge

- Top: a b g b c d f
- Bottom: g d f e a c

Sort Left Edge:
- a:1—5
- g:1—3
- b:2—4
- d:2—6
- f:3—7
- e:4—7
- c:5—6

Example: Left-Edge

- Top: a b g b c d f
- Bottom: g d f e a c

Sort Left Edge:
- g:1—3
- d:2—6
- e:4—7
- c:5—6

Track 0: a:1—5
Track 1: g:1—3, e:4—7
Track 2: b:2—4, c:5—6
Track 3: d:2—6
Track 4: f:3—7
Constrained Left-Edge

1. Construct VCG
2. Sort nets on leftmost end position
3. Start new track; end=0
4. While there are nets that have
   ✓ No descendents in VCG
   ✓ And left edge > end
   1. Place net on track and update end
   2. Delete net from list, VCG
5. If there are still nets left to route, return to 2

Example: Constrained Left-Edge

• Top: a b g b c d f
• Bottom: g d f e a c e
• Vertical Constraints
  • Also give a lower bound on routed channel width
    – Channel width >= channel density
    – Channel width >= height of VCG graph

Example: ... 

• Top: a b g b c d f
• Bottom: g d f e a c e
• Sort Left Edge:
  – a:1—5
  – g:1—3
  – b:2—4
  – d:2—6
  – f:3—7
  – e:4—7
  – c:5—6
• Track 0:
  • a:4—7
• Track 1:
  • f:3—7
• Track 2:
  • g:1—3
• Track 3:
  • a:1—5
• Track 4:
  • c:5—6
• Track 5:
  • d:2—6
• Track 6:
  • b:2—4

Example 2: ... 

• Top: a a b e d g c
• Bottom: b c d e f g f
• Sort Left Edge:
  – b:1—4
  – a:1—3
  – c:2—8
  – d:3—6
  – e:4—5
  – f:5—8
  – c:6—7

Example: Left-Edge

• Top: a b g b c d f
• Bottom: g d f e a c e
• Nets:
  – a:1—5
  – b:2—4
  – c:5—6
  – d:2—6
  – e:4—7
  – f:3—7
  – g:1—3
Example 2: …

- Top:  a a b e d g c
- Bottom:  b c d e f g f f
- Sort Left Edge:
  - b:1—4
  - a:1—3
  - e:4—5
  - f:5—8
  - g:6—7

VCG Cycles

- Top:  a a b
- Bottom:  b c a
- VCG:

Track 0: f
Track 1: c
Track 2: e, g
Track 3: b
Track 4: d
Track 5: a

VCG Cycles

- No channel ordering satisfies VCG
- Must relax artificial constraint of single horizontal track per signal
- Dogleg: split horizontal run into multiple track segments
- In general, can reduce track requirements

Dogleg Cycle Elimination

- Top:  a a b
- Bottom:  b c a
- VCG:

- Top:  a1 a1/a2  b
- Bottom:  b  c  a2
- VCG:

Dogleg Cycle Elimination

- Top:  a1 a1/a2  b
- Bottom:  b  c  a2

Dogleg Algorithm

1. Break net into segments at pin positions
2. Build VCG based on segments
3. Run constrained on segments rather than full wires
Dogleg Example (no cycle)
- Top: 1 1 2 - 2 3
- Bottom: 2 3 - 3 4

1 1 2/2b – 2b 3b
2a 3a – 3a/b 4 4

[note: switch to numbers for terminals]

No Dogleg
- Top: 1 1 2 - 2 3
- Bottom: 2 3 - 3 4

With Dogleg
- Top: 1 1 2/2b – 2b 3b
- Bottom: 2a 3a – 3a/b 4 4

Doglegs
- Exploiting dogleg
  - Introduces more freedom
  - Can reduce track requirements
    • Reduces height of VCG
- In general, any unused vertical track could support some dogleg

Channel Abstraction

Doglegs
- Exploiting dogleg
  - Introduces more freedom
  - Can reduce track requirements
- In general, any unused vertical track could support some dogleg
  - How select which signal uses track for dogleg?
    • Creates a larger optimization problem
  - Might support multiple?
**Other Freedoms**

- Swap equivalent pins
  - *E.g.* nand inputs equivalent
- Mirror cells
  - if allowed electrically
- Choose among cell instances
  - Permute pins

**Exploit Freedom To**

- Reduce channel density
- Reduce/Eliminate vertical constraints
  - Cycles
  - VCG height

**Over The Cell**

- Limit cell to lower metal
  - Maybe only up to M1
- Can route over with higher metal

**Example: OTC**

- Top: 0 1 6 1 2 3 5
- Bottom: 6 3 5 4 0 2 4

**Over The Cell**

- Compute maximal independent set
  - To find nets can be routed in 1 layer (planar) over cell
  - MIS can be computed in O(n^2) time with dynamic programming
- Then route residual connections in channel
- Works on 2-metal if only M1 in cell
  - Feedthrus in M1

**Multilayer**

- With 3 layer
  - Can run channel over cells
  - Put Terminals in center of cell
Standard Cell Area

- All cells uniform height
- Width of channel determined by routing

Route Over Cells

- If channel width < cell height
  - Routing completely on top of cells
- If channel width > cell height
  - Cell area completely hidden under routing channel
  - More typical case
    - Especially for large rows

Channel Over Cell

Summary

- Decompose Routing
- Channel Routing
- Left-Edge
- Vertical Constraints
- Exploiting Freedom
  - Dogleg, pin swapping
  - Routing over logic

Big Ideas

- Decompose Problem
  - Divide and conquer
- Interrelation of components
- Structure: special case can solve optimally
- Technique: Greedy algorithm
- Use greedy as starting point for more general algorithm

Admin

- Next week Spring Break
- Reading for Monday after break online
- Andre out week after break
  - Monday: Guest lecture
  - Wednesday: No class (no midterm)
- Assign 7, 8 on routing out
