A collaborative project to design a statically-typed functional programming language based on dependent type theory.

Work-in-progress

# Why Dependent Types?

- *Lightweight verification*: Dependent types express application-specific program invariants that are beyond the scope of existing type systems.
- *Expressiveness*: Dependent types enable flexible interfaces, allowing more programs to be statically checked.

# Why Dependent Types?

- *Lightweight verification*: Dependent types express application-specific program invariants that are beyond the scope of existing type systems.
- *Expressiveness*: Dependent types enable flexible interfaces, allowing more programs to be statically checked.
- *Uniformity*: Full-spectrum dependent types provide the same syntax and semantics for program computations, type-level computations, and proofs.

# A programming language, not a logic

Start with a general purpose, call-by-value, functional programming language and strengthen its type system.

- Want to draw programmers from Haskell and ML
- Want existing code to work with minor modification
- Want to support incremental verification... only provide the strongest guarantees about the most critical code
- Ease of programming more important than completeness of verification

# On the shoulders of giants

Not the first to propose programming with dependent types

- Agda, Epigram, Coq, Lego, Nuprl

# On the shoulders of giants

Not the first to propose programming with dependent types

- Agda, Epigram, Coq, Lego, Nuprl

Not the first functional language to incorporate ideas from  
Type Theory

- GHC, Ur, Sage, ATS,  $\Omega$ mega, DML

# On the shoulders of giants

Not the first to propose programming with dependent types

- Agda, Epigram, Coq, Lego, Nuprl

Not the first functional language to incorporate ideas from Type Theory

- GHC, Ur, Sage, ATS,  $\Omega$ mega, DML

Not the first to propose a full-spectrum functional programming language based on dependent types

- Guru, Cayenne, Cardelli “A Polymorphic  $\lambda$ -calculus with Type:Type”

## Why call-by-value?

- Have to choose something. Want to include nontermination so the order of evaluation makes a difference

## Why call-by-value?

- Have to choose something. Want to include nontermination so the order of evaluation makes a difference
- Good cost model. Programmers can better predict the running time and space usage of their programs

## Why call-by-value?

- Have to choose something. Want to include nontermination so the order of evaluation makes a difference
- Good cost model. Programmers can better predict the running time and space usage of their programs
- Distinction between values and computations built into the language. Variables stand for values, not computations

# A programming language, not a logic

Can't use Curry-Howard Isomorphism to interpret this language as a logic.

## A seeming contradiction

How can we have a full-spectrum, dependently-typed language based on an inconsistent logic?

## Syntactic type soundness

Main property of typed programming languages is proven by an *elementary syntactic* argument and extends in a straightforward manner to modern language features (such as references, concurrency, exceptions, continuations, etc.)

# Syntactic type soundness

Main property of typed programming languages is proven by an *elementary syntactic* argument and extends in a straightforward manner to modern language features (such as references, concurrency, exceptions, continuations, etc.)

## Theorem (Syntactic type soundness)

If  $\vdash a : A$  then either  $a$  diverges, or  $a \rightsquigarrow_{\text{cbv}}^* v$  and  $\vdash v : A$ .

Type soundness gives us a form of *partial correctness*

## Partial correctness

Can give a logical interpretation for *values* based on partial correctness:

$$\vdash a : \Sigma x : \mathbf{Nat}. \text{even } x = \text{true}$$

If  $a$  terminates, then it *must* produce a pair of a natural number and a *proof* that the result is even.

## Partial correctness

Can give a logical interpretation for *values* based on partial correctness:

$$\vdash a : \Sigma x : \mathbf{Nat}. \text{even } x = \text{true}$$

If  $a$  terminates, then it *must* produce a pair of a natural number and a *proof* that the result is even.

But...

$$\vdash a : \Sigma x : \mathbf{Nat}. (\text{even } x = \text{true}) \rightarrow (x = 3)$$

# Total correctness

Partial correctness is not enough

- Can't compile this language efficiently (have to run proofs)
- Users are willing to work harder for stronger guarantees

# From partial correctness to total correctness

Plan for the rest of the talk:

- Part I: present a full-spectrum CBV language that satisfies type soundness only
- Part II: identify a “logical” sublanguage and discuss the interactions between the two parts

# From partial correctness to total correctness

Plan for the rest of the talk:

- Part I: present a full-spectrum CBV language that satisfies type soundness only
- Part II: identify a “logical” sublanguage and discuss the interactions between the two parts

Not covered by this talk:

- How to make type checking decidable by adding annotations to the syntax
- How to make program development feasible by inferring annotations

Part I : A call-by-value  
programming language with  
dependent types

# Uniform language

Types, terms, kinds defined using the same syntax

## Syntax

$$\begin{aligned} a, b, A, B & ::= \star \mid \text{Nat} \mid (x:A) \rightarrow B \\ & \quad \mid 0 \mid \text{S } a \mid \text{case } a \text{ of } \{0 \Rightarrow a_1; \text{S } x \Rightarrow a_2\} \\ & \quad \mid x \mid \text{rec } f \ x.a \mid a \ b \end{aligned}$$
$$\begin{aligned} v, u & ::= \star \mid \text{Nat} \mid (x:A) \rightarrow B \\ & \quad \mid 0 \mid \text{S } v \\ & \quad \mid x \mid \text{rec } f \ x.a \end{aligned}$$

Use standard abbreviations:

- $\lambda x.a$  for  $\text{rec } f \ x.a$  when  $f$  is not free in  $a$
- $A \rightarrow B$  for  $(x:A) \rightarrow B$  when  $x$  is not free in  $B$

# Call-by-value operational semantics

$$\boxed{a \rightsquigarrow_{\text{cbv}} b}$$

$$\frac{}{(\text{rec } f \ x.a) \ v \rightsquigarrow_{\text{cbv}} [v/x][\text{rec } f \ x.a/f]a}$$

$$\frac{}{\text{case } 0 \text{ of } \{0 \Rightarrow a_1; \text{S } x \Rightarrow a_2\} \rightsquigarrow_{\text{cbv}} a_1}$$

$$\frac{}{\text{case } (\text{S } v) \text{ of } \{0 \Rightarrow a_1; \text{S } x \Rightarrow a_2\} \rightsquigarrow_{\text{cbv}} [v/x]a_2}$$

# Example

## Polymorphic application

$$app : (x : \star) \rightarrow (f : x \rightarrow x) \rightarrow (z : x) \rightarrow x$$
$$app = \lambda x. \lambda f. \lambda z. f \ z$$
$$app \ \text{Nat} \ (\lambda x. x) \ 0 \equiv 0$$

## Expressive example

$$\mathit{zeroApp} = \lambda g. \lambda z. g$$
$$\mathit{oneApp} = \lambda g. \lambda z. g z$$
$$\mathit{twoApp} = \lambda g. \lambda z. g z z$$
$$\begin{aligned} \mathit{nApp} = \text{rec } f \ n. \text{ case } n \text{ of} \\ \quad \{ 0 \quad \Rightarrow \lambda g. \lambda z. g ; \\ \quad \text{S } m \Rightarrow \lambda g. \lambda z. f \ m \ (g \ z) \ z \} \end{aligned}$$

## Expressive example

$$\begin{aligned} \mathit{zeroApp} & : \text{Nat} \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{zeroApp} & = \lambda g. \lambda z. g \\ \mathit{oneApp} & : (\text{Nat} \rightarrow \text{Nat}) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{oneApp} & = \lambda g. \lambda z. g \ z \\ \mathit{twoApp} & : (\text{Nat} \rightarrow \text{Nat} \rightarrow \text{Nat}) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{twoApp} & = \lambda g. \lambda z. g \ z \ z \end{aligned}$$
$$\begin{aligned} \mathit{nApp} & = \text{rec } f \ n. \text{ case } n \text{ of} \\ & \quad \{ 0 \quad \Rightarrow \lambda g. \lambda z. g ; \\ & \quad \quad S \ m \Rightarrow \lambda g. \lambda z. f \ m \ (g \ z) \ z \} \end{aligned}$$

## Expressive example

$$\begin{aligned} \mathit{zeroApp} & : \text{Nat} \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{zeroApp} & = \lambda g. \lambda z. g \\ \mathit{oneApp} & : (\text{Nat} \rightarrow \text{Nat}) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{oneApp} & = \lambda g. \lambda z. g \ z \\ \mathit{twoApp} & : (\text{Nat} \rightarrow \text{Nat} \rightarrow \text{Nat}) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{twoApp} & = \lambda g. \lambda z. g \ z \ z \end{aligned}$$
$$\begin{aligned} \mathit{nApp} & : (n : \text{Nat}) \rightarrow (\text{N } n) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \mathit{nApp} & = \text{rec } f \ n. \text{ case } n \text{ of} \\ & \quad \{ 0 \quad \Rightarrow \lambda g. \lambda z. g ; \\ & \quad \text{S } m \Rightarrow \lambda g. \lambda z. f \ m \ (g \ z) \ z \} \end{aligned}$$

## Expressive example

$$\begin{aligned} \text{zeroApp} & : \text{Nat} \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \text{zeroApp} & = \lambda g. \lambda z. g \\ \text{oneApp} & : (\text{Nat} \rightarrow \text{Nat}) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \text{oneApp} & = \lambda g. \lambda z. g \ z \\ \text{twoApp} & : (\text{Nat} \rightarrow \text{Nat} \rightarrow \text{Nat}) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ \text{twoApp} & = \lambda g. \lambda z. g \ z \ z \end{aligned}$$
$$\begin{aligned} N & : \text{Nat} \rightarrow * \\ N & = \text{rec } f \ n. \text{ case } n \text{ of} \\ & \quad \{ 0 \quad \Rightarrow \text{Nat} ; \\ & \quad \quad S \ m \Rightarrow \text{Nat} \rightarrow f \ m \} \\ nApp & : (n : \text{Nat}) \rightarrow (N \ n) \rightarrow \text{Nat} \rightarrow \text{Nat} \\ nApp & = \text{rec } f \ n. \text{ case } n \text{ of} \\ & \quad \{ 0 \quad \Rightarrow \lambda g. \lambda z. g ; \\ & \quad \quad S \ m \Rightarrow \lambda g. \lambda z. f \ m \ (g \ z) \ z \} \end{aligned}$$

# Typing relation

$\Gamma \vdash a : A$

General recursion

$$\frac{\Gamma, y : A, f : (y : A) \rightarrow B \vdash a : B}{\Gamma \vdash \text{rec } f \ y.a : (y : A) \rightarrow B}$$

Type is a type

$$\frac{}{\vdash \star : \star}$$

## Conversion

Because types depend on programs, we want to identify types that contain equivalent programs.

$$\text{Vec Nat } (1 + 2) \equiv \text{Vec Nat } 3$$

Expressions can be assigned any equivalent type

### Conversion

$$\frac{\Gamma \vdash a : A \quad A \equiv B \quad \Gamma \vdash B : \star}{\Gamma \vdash a : B}$$

## Conversion

Because types depend on programs, we want to identify types that contain equivalent programs.

$$\text{Vec Nat } (1 + 2) \equiv \text{Vec Nat } 3$$

Expressions can be assigned any equivalent type

### Conversion

$$\frac{\Gamma \vdash a : A \quad A \equiv B \quad \Gamma \vdash B : \star}{\Gamma \vdash a : B}$$

But what does it mean for types to be equal?

# Definitional Equality

- Based on operational semantics (hence undecidable)
- Ideally: identify all terms that are contextually equivalent to each other
- For now: close step relation under reflexivity, symmetry, transitivity and substitutivity
- Strictly computational, properties shown via rewriting

$$a \equiv b$$

$$\frac{a_1 \rightsquigarrow_{\text{cbv}} a_2}{a_1 \equiv a_2} \qquad \frac{}{a \equiv a} \qquad \frac{a_1 \equiv a_2}{a_2 \equiv a_1}$$

$$\frac{a_1 \equiv a_2 \quad a_2 \equiv a_3}{a_1 \equiv a_3} \qquad \frac{a_1 \equiv a_2}{[a_1/x]A \equiv [a_2/x]A}$$

## Internalizing equality

Internalize definitional equality as a proposition, with a trivial proof

$a, b, A, B ::= \dots \mid a = b \mid \text{join}$

$$\frac{a \equiv b \quad \Gamma \vdash a = b : \star}{\Gamma \vdash \text{join} : a = b}$$

$$\frac{\Gamma \vdash a : A \quad \Gamma \vdash b : B}{\Gamma \vdash a = b : \star}$$

## Conversion and propositional equality

Extend conversion rule to propositional equality

$$\frac{\Gamma \vdash a : A \quad \Gamma \vdash v : A = B}{\Gamma \vdash a : B}$$

- Subsumes previous conversion rule (using join as the value)
- Conversion is implicit. Terms that differ only in convertible types are trivially equal
- Proof must be a *value* because of partial correctness
- Don't care which value it is

## Why can we do this?

Type soundness follows from the following property (which can be proven *syntactically*):

Lemma (Soundness of propositional equality)

If  $\vdash v : A_1 = A_2$  then  $A_1 \equiv A_2$ .

## The cost of CBV

Call-by-value semantics adds extra hypothesis to application rule:

$$\frac{\Gamma \vdash a : (x:A) \rightarrow B \quad \Gamma \vdash b : A \quad \Gamma \vdash [b/x]B : \star}{\Gamma \vdash a b : [b/x]B}$$

## The cost of CBV

Call-by-value semantics adds extra hypothesis to application rule:

$$\frac{\Gamma \vdash a : (x:A) \rightarrow B \quad \Gamma \vdash b : A \quad \Gamma \vdash [b/x]B : \star}{\Gamma \vdash a b : [b/x]B}$$

If  $b$  is a non-value, the rule must make sure that  $x$  was never treated as a value in  $B$ .

# Implicit arguments

Some values have no runtime effect.

Useful for:

- Parametric polymorphism  $(x : \star) \rightarrow x \rightarrow x$
- Preconditions  $(x : \text{Nat}) \rightarrow \neg(x = 0) \rightarrow \text{Nat}$

Want to elide them from the syntax of terms

$app (\lambda x.x) 0$  instead of  $app \text{Nat} (\lambda x.x) 0$

# Implicit arguments

Add implicit abstraction type

$$a, b, A, B ::= \dots \mid [x : A] \rightarrow B$$

but... can only generalize over values

$$\frac{\Gamma, x : A \vdash v : B \quad x \notin \text{FV}v}{\Gamma \vdash v : [x : A] \rightarrow B}$$

...can only instantiate with values

$$\frac{\Gamma \vdash a : [x : A] \rightarrow B \quad \Gamma \vdash v : A}{\Gamma \vdash a : [v/x]B}$$

## Value restrictions are annoying

Suppose we write a program that *proves* the following fact about natural numbers:

$$f : (x : \text{Nat}) \rightarrow (y : \text{Nat}) \rightarrow (x = \text{S } y) \rightarrow \neg(x = 0)$$

However, a use of this lemma “ $f \ x \ y \ z$ ” is not a value and cannot be erased.

## Value restrictions are annoying

Suppose we write a program that *proves* the following fact about natural numbers:

$$f : (x : \text{Nat}) \rightarrow (y : \text{Nat}) \rightarrow (x = \text{S } y) \rightarrow \neg(x = 0)$$

However, a use of this lemma “ $f \ x \ y \ z$ ” is not a value and cannot be erased.

Must first use an explicit argument to evaluate it to a value, even though the value is irrelevant.

# Taking stock

- Make type checking decidable by adding annotations to the syntax
- Make program development feasible by inferring annotations

# Taking stock

- Make type checking decidable by adding annotations to the syntax
- Make program development feasible by inferring annotations
- ...but, irrelevant computations remain at runtime

# Taking stock

- Make type checking decidable by adding annotations to the syntax
- Make program development feasible by inferring annotations
- ...but, irrelevant computations remain at runtime
- ...slowing execution

# Taking stock

- Make type checking decidable by adding annotations to the syntax
- Make program development feasible by inferring annotations
- ...but, irrelevant computations remain at runtime
- ...slowing execution
- ...weakening equivalence

# Taking stock

- Make type checking decidable by adding annotations to the syntax
- Make program development feasible by inferring annotations
- ...but, irrelevant computations remain at runtime
- ...slowing execution
- ...weakening equivalence
- ...and weakening static guarantees

# Part II : A logical sublanguage

## A logical language

- There is a logically-consistent sublanguage hiding in here.

# A logical language

- There is a logically-consistent sublanguage hiding in here.
- How do we identify it?

# A logical language

- There is a logically-consistent sublanguage hiding in here.
- How do we identify it?
- We use the type system!

# A logical language

- There is a logically-consistent sublanguage hiding in here.
- How do we identify it?
- We use the type system!
- Annotate typing judgement to specify the *logical* language or the *programmatic* language.

# A logical language

- There is a logically-consistent sublanguage hiding in here.
- How do we identify it?
- We use the type system!
- Annotate typing judgement to specify the *logical* language or the *programmatic* language.

New typing judgement form:

$$\Gamma \vdash^{\theta} a : A \quad \text{where} \quad \theta ::= L \mid P$$

# Subsumption

Logical language is a *sublanguage* of the programmatic language.

$$\frac{\Gamma \vdash^L a : A}{\Gamma \vdash^P a : A}$$

It guarantees stronger properties about its expressions.

## Theorem (Syntactic type soundness)

If  $\vdash^P a : A$  then either  $a$  diverges, or  $a \rightsquigarrow_{\text{cbv}}^* v$  and  $\vdash^P v : A$ .

## Theorem (Semantic consistency)

If  $\vdash^L a : A$  then  $a \rightsquigarrow_{\text{cbv}}^* v$  and  $\vdash^L v : A$

# Expressive features must be programmatic

Some capabilities only available for the programmatic language

## Type-In-Type

$$\frac{}{\vdash^P \star : \star}$$

## General recursion

$$\frac{\begin{array}{l} \Gamma \vdash^P (x :^\theta A) \rightarrow B : \star \\ \Gamma, x :^\theta A, f :^P (x :^\theta A) \rightarrow B \vdash^P b : B \end{array}}{\Gamma \vdash^P \text{rec } f \ x.b : (x :^\theta A) \rightarrow B}$$

## What does the logical language look like?

Logical functions should not be recursive...

$$\frac{\Gamma \vdash^{\text{L}} (x :^{\theta} A) \rightarrow B : \star \quad \Gamma, x :^{\theta} A \vdash^{\text{L}} b : B}{\Gamma \vdash^{\text{L}} \text{rec } f \ x.b : (x :^{\theta} A) \rightarrow B}$$

# What does the logical language look like?

Logical functions should not be recursive...

$$\frac{\Gamma \vdash^{\perp} (x :^{\theta} A) \rightarrow B : \star \quad \Gamma, x :^{\theta} A \vdash^{\perp} b : B}{\Gamma \vdash^{\perp} \text{rec } f \ x.b : (x :^{\theta} A) \rightarrow B}$$

...except for primitive recursion over natural numbers

$$\frac{\Gamma, x :^{\perp} \text{Nat} \vdash^{\perp} B : \star \quad \Gamma, x :^{\perp} \text{Nat}, f :^{\perp} (y :^{\perp} \text{Nat}) \rightarrow [z :^{\perp} (\text{S } y) = x] \rightarrow [y/x]B \vdash^{\perp} b : B}{\Gamma \vdash^{\perp} \text{rec } f \ x.b : (x :^{\perp} \text{Nat}) \rightarrow B}$$

## Mixing the sublanguages

Programmatic functions can have logical parameters:

$$\frac{\begin{array}{l} \Gamma \vdash^{\text{P}} (x :^{\text{L}} A) \rightarrow B : \star \\ \Gamma, x :^{\text{L}} A, f :^{\text{P}} (x :^{\text{L}} A) \rightarrow B \vdash^{\text{P}} b : B \end{array}}{\Gamma \vdash^{\text{P}} \text{rec } f \ x.b : (x :^{\text{L}} A) \rightarrow B}$$

Such arguments are logical “proofs” that the preconditions of the function are satisfied.

## Mixing the sublanguages

Programmatic functions can have logical parameters:

$$\frac{\begin{array}{l} \Gamma \vdash^{\text{P}} (x :^{\text{L}} A) \rightarrow B : \star \\ \Gamma, x :^{\text{L}} A, f :^{\text{P}} (x :^{\text{L}} A) \rightarrow B \vdash^{\text{P}} b : B \end{array}}{\Gamma \vdash^{\text{P}} \text{rec } f \ x.b : (x :^{\text{L}} A) \rightarrow B}$$

Such arguments are logical “proofs” that the preconditions of the function are satisfied.

These arguments can be implicit, even if they are not values.

# Freedom of Speech

Logical functions can have programmatic parameters:

$$\frac{\Gamma \vdash^L (x :^P A) \rightarrow B : \star \quad \Gamma, x :^P A \vdash^L b : B}{\Gamma \vdash^L \text{rec } f \ x.b : (x :^P A) \rightarrow B}$$

# Freedom of Speech

Logical functions can have programmatic parameters:

$$\frac{\Gamma \vdash^L (x :^P A) \rightarrow B : \star \quad \Gamma, x :^P A \vdash^L b : B}{\Gamma \vdash^L \text{rec } f \ x.b : (x :^P A) \rightarrow B}$$

Application restricted to terminating arguments.

$$\frac{\Gamma \vdash^L a : (x :^P A) \rightarrow B \quad \Gamma \vdash_{\downarrow} b : A \quad \Gamma \vdash^L [b/x]B : \star}{\Gamma \vdash^L a \ b : [b/x]B}$$

Total arguments are either logical or values.

$$\frac{\Gamma \vdash^L a : A}{\Gamma \vdash_{\downarrow} a : A} \quad \frac{\Gamma \vdash^P v : A}{\Gamma \vdash_{\downarrow} v : A}$$

# Conversion

- Conversion available for both languages
- Equality proof must be total

$$\frac{\Gamma \vdash^\theta a : A \quad \Gamma \vdash_\downarrow b : A = B}{\Gamma \vdash^\theta a : B}$$

## Shared values

Some values are shared between the two languages.

## Shared values

Some values are shared between the two languages.  
For example, all natural numbers are values in the logical language as well as in the programmatic language.

$$\frac{}{\vdash^L \text{Nat} : \star} \quad \frac{}{\vdash^L 0 : \text{Nat}} \quad \frac{\Gamma \vdash^\theta n : \text{Nat}}{\Gamma \vdash^\theta \text{S } n : \text{Nat}}$$

## Shared values

Some values are shared between the two languages.  
For example, all natural numbers are values in the logical language as well as in the programmatic language.

$$\frac{}{\vdash^L \text{Nat} : \star} \quad \frac{}{\vdash^L 0 : \text{Nat}} \quad \frac{\Gamma \vdash^\theta n : \text{Nat}}{\Gamma \vdash^\theta \text{S } n : \text{Nat}}$$

This means that it is sound to treat a variable of type `Nat` as logical, no matter what it is assumed to be in the context.

$$\frac{\Gamma \vdash^P x : \text{Nat}}{\Gamma \vdash^L x : \text{Nat}}$$

## Uniform equality

Equality proofs are also shared.

All equality proofs and propositions are logical, no matter what sort of terms they equate.

$$\frac{\Gamma \vdash^{\text{P}} a : A \quad \Gamma \vdash^{\text{P}} b : B}{\Gamma \vdash^{\text{L}} a = b : \star} \quad \frac{\Gamma \vdash^{\text{L}} a = b : \star \quad a \equiv b}{\Gamma \vdash^{\text{L}} \text{join} : a = b}$$

## Uniform equality

Equality proofs are also shared.

All equality proofs and propositions are logical, no matter what sort of terms they equate.

$$\frac{\Gamma \vdash^{\text{P}} a : A \quad \Gamma \vdash^{\text{P}} b : B}{\Gamma \vdash^{\text{L}} a = b : \star} \quad \frac{\Gamma \vdash^{\text{L}} a = b : \star \quad a \equiv b}{\Gamma \vdash^{\text{L}} \text{join} : a = b}$$

We can treat a programmatic variable as a logical equality proof.

$$\frac{\Gamma \vdash^{\text{P}} x : A = B}{\Gamma \vdash^{\text{L}} x : A = B}$$

This supports incremental verification. We can have a partial function return an equality proof and then use that to satisfy the preconditions of any part of the code.

# Conclusion

## Future work

- What logical system should we use? Predicative? Impredicative? Large Eliminations? Induction-Recursion?
- Interaction with classical reasoning: allow proofs to branch on whether a program halts or diverges
- Strengthen definitional and propositional equality
- Elaboration to an annotated language

# Summary

- Can have full-spectrum dependently-typed language with nontermination, effects, etc.
- Call-by-value semantics permits “partial correctness”
- Logical and programmatic languages can interact
  - All proofs are programs
  - Logic can talk about programs
  - Shared values can be passed from programs to the logic
