Fall 2005

28 November

- ◆ This week: Chapter 18/19
- ◆ Next week: Chapter 19/Review
- ◆ Final exam: Wednesday, December 14th

Plans

On to Objects

We've spent the semester developing tools for defining and reasoning about a variety of programming language features. Now it's time to **use** these tools for something more ambitious.

A Change of Pace

Case study: object-oriented programming

Plan:

1. Identify some characteristic “core features” of object-oriented programming
2. Develop two different analyses of these features:
 - (a) A **translation** into a lower-level language
 - (b) A **direct**, high-level formalization of a simple object-oriented language
 (“Featureweight Java”)

Our first goal will be to show how many of the basic features of object-oriented languages can be understood as „derived forms“ in a lower-level language with a rich collection of primitive features:

- dynamic dispatch
- encapsulation of state
- inheritance
- late binding (this)
- super

The Translational Analysis

For simple objects and classes, this translational analysis works very well. When we come to more complex features (in particular, classes with **self**), it becomes less satisfactory, leading us to the more direct treatment in the following chapter.

Concepts

The Essence of Objects

What “is” object-oriented programming?

The Essence of Objects

What “is” object-oriented programming?

This question has been a subject of debate for decades. Such arguments are always inconclusive and seldom very interesting.

What „is“ object-oriented programming?
This question has been a subject of debate for decades. Such arguments are always inconclusive and seldom very interesting.
However, it is easy to identify some core features that are shared by most OO languages and that, together, support a distinctive and useful programming style.

The Essence of Objects

Perhaps the most basic characteristic of object-oriented programming is **dynamic dispatch**: when an operation is invoked on an object, the ensuing behavior depends on the object itself, rather than being fixed once and for all (as when we apply a function to an argument).

Two objects of the **same type** (i.e., responding to the same set of operations) may be implemented internally in **completely different ways**.

Dynamic dispatch

Note: (`new B() .m()`) and (`new C() .m()`) invoke completely different code!

```
}

int m() { x = x-10; return x; }

class C extends A {

}

int m() { x = x+5; return x; }

class B extends A {

}

int u() { x = x-1; return x; }

int m() { x = x+1; return x; }

int x = 0;

class A {
```

Example

In most OO languages, each object consists of some internal state **encapsulated** with a collection of method implementations operating on that state.

- ◆ state **inaccessible** from outside the object
- ◆ state **directly accessible** to methods

Encapsulation

The code `(new B()).x` is not allowed.

```
}

class C extends A {
    int m() { x = x-10; return x; }

}

class B extends A {
    int m() { x = x+5; return x; }

}

class A {
    protected int x = 0;

    int u() { x = x-1; return x; }
    int m() { x = x+1; return x; }
}
```

In Java, encapsulation of internal state is optional. For full encapsulation, fields must be marked `protected`:

Example

The encapsulation of state with methods offered by objects is a form of information hiding.
A somewhat different form of information hiding is embodied in the notion of an abstract data type (ADT).

Side note: Objects vs. ADTs

- ◆ A collection of operations for creating and manipulating elements of type **X**.
 - ◆ A **hidden** representation type **X**
- An ADT comprises:
- Similar** to OO encapsulation in that only the operations provided by the ADT are allowed to directly manipulate elements of the abstract type.
- But **different** in that there is just one (hidden) representation type and just one implementation of the operations — no dynamic dispatch.
- Both styles have advantages.
- N.b. in the OO community, the term „abstract data type“ is often used as more or less a synonym for „object type.“ This is unfortunate, since it confuses two rather different concepts.

Side note: Objects vs. ADTs

The “type” (or “interface” in Smalltalk terminology) of an object is just the set of operations that can be performed on it (and the types of their parameters and results); it does not include the internal representation. Object interfaces fit naturally into a subtype relation. An interface listing more operations is “better” than one listing fewer operations.

This gives rise to a natural and useful form of polymorphism: we can write one piece of code that operates uniformly on any object whose interface is “at least as good as I ” (i.e., any object that supports at least the operations in I).

Subtyping and Encapsulation

```
int w = d.p (new C());  
int z = d.p (new B());  
D d = new D();  
...  
{  
    int p (A myA) { return myA.m(); }  
}
```

Example

Inheritance

Objects that share parts of their interfaces will typically (though not always)

share parts of their behaviors.

To avoid duplication of code, want to write the implementations of these behaviors in just one place.

← inheritance

objects.

N.b.: some OO languages offer an alternative mechanism, called **delegation**, which allows new objects to be derived by refining the behavior of existing objects.

◆ **refined** to create new classes ("subclasses")

◆ **instantiated** to create new objects ("instances")

A class is a data structure that can be

Basic mechanism of inheritance: **classes**

Inheritance

An instance of **B** has methods **m**, **u**, and **o**. The first two are inherited from **A**.

```
protected int x = 0;  
class A {  
    int m() { x = x+1; return x; }  
    int u() { x = x-1; return x; }  
    int o() { x = x*10; return x; }  
}  
class B extends A {  
}
```

Example

Most OO languages offer an extension of the basic mechanism of classes and inheritance called **Late binding** or **open recursion**.

Late binding allows a method within a class to call another method via a special „pseudo-variable” **self**. If the second method is overridden by some subclass, then the behavior of the first method automatically changes as well.

Though quite useful in many situations, late binding is rather tricky, both to define (as we will see) and to use appropriately. For this reason, it is sometimes deprecated in practice.

Late binding

```
What does (new F()).a() return?  
What does (new E()).a() return?  
  
{  
    int m() { x = x+100; return x; }  
    class F extends E {  
        {  
            int a() { x = x-1; return this.m(); }  
            int m() { x = x+1; return x; }  
            protected int x = 0;  
        }  
    }  
}
```

Examples

It is sometimes convenient to “re-use” the functionality of an overridden method. Java provides a mechanism called **super** for this purpose.

Calling “super”

What does `(new G()).a()` return?

```
int m() { x = x+100; return super.m(); }
class G extends E {
}

int a() { x = x-1; return this.m(); }
int m() { x = x+1; return x; }
protected int x = 0;
class E {
```

Example

(in the lambda-calculus) ...

Getting down to details

How do we encode objects in the Lambda-calculus?

```
class Counter {  
    protected int x = 1; // Hidden state  
    int get() { return x; }  
    void inc() { x++; }  
    void inc3(Counter c) {  
        c.inc(); c.inc(); c.inc();  
    }  
    Counter c = new Counter();  
    inc3(c);  
    c.get();  
}
```

Simple objects with encapsulated state

```
c = let x = ref 1 in
      {get : unit -> nat, inc : unit -> unit};
      inc = λ : unit. x := succ (x);
      get = λ : unit. x;
```

Objects

```
inc3 = Ac:Counter. (c.inc unit; c.inc unit; c.inc unit);  
inc3 : Counter → Unit  
inc3 c; inc3 c; c.get unit);  
inc3 c; inc3 c; c.get unit);  
==== 7
```

Objects

```
newCounter : Unit → Counter  
= λ:Unit. Let x = ref 1 in  
{get = λ:Unit. ix,  
inc = λ:Unit. x:=succ(ix)};
```

Object Generators

The local variable `x` has type `CounterRep = {x: Ref Nat}`

```
inc =  $\lambda$ :Unit. x.x:=succ(i(x.x));  
get =  $\lambda$ :Unit. i(x.x),  
 $\lambda$ :Unit. Let x = {x=ref l} in  
newCounter =
```

It will be convenient (later) to group these into a single record.

Rather than a single reference cell, the states of most objects consist of a number of **instance variables** or **fields**.

Grouping Instance Variables

```
    rc.get();  
    inc3(rc);  
    rc.reset();  
    inc3(rc);  
ResetCounter rc = new ResetCounter();  
  
}  
  
void reset() { x = 1; }  
class ResetCounter extends Counter {  
  
}  
void inc() { x++; }  
int get() { return x; }  
protected int x = 1;  
class Counter {
```

Subtyping and Inheritance

```
newResetCounter : Unit → ResetCounter
= λ : Unit. Let x = {x = ref () in
  newResetCounter =
    λ : Unit. {get : Unit → Nat, inc : Unit → Unit, reset : Unit → Unit} ;
    {get = λ : Unit. i (x .x),
     inc = λ : Unit. x .x := succ (i (x .x)),
     reset = λ : Unit. x .x := 1};
```

Subtyping

← 4

rc = newResetCounter unit;

Subtyping

(inc3 rc; rc.reset unit; inc3 rc; rc.get unit);

The definitions of `newCounter` and `newResetCounter` are identical except for the `reset` method.

This violates a basic principle of software engineering:

Each piece of behavior should be implemented in just one place in the code.

Simple Classes

Idea: could we just re-use the methods of some existing object to build a new object?

```
resetCounterFromCounter =  
    AC:Counter. Let x = {x = ref l} in  
        {get = c.get,  
         inc = c.inc,  
         reset = A_.Unit. x.x:=l};
```

Reusing Methods

classes

No: This doesn't work properly because the `reset` method does not have access to the local variable `x` of the original counter.

```
reset = A[Unit].x:=1};  
inc   = C.inc,  
get   = C.get,  
Ac:Counter. Let x = {x = ref l} in  
resetCounterFromCounter =  
object?
```

Idea: could we just re-use the methods of some existing object to build a new

Reusing Methods

- A class is a run-time data structure that can be
1. instantiated to yield new objects
 2. extended to yield new classes

Classes

```

    ⇐ newCounter : Unit → Counter
    counterClass x;
    ∀-:Unit. Let x = {x=ref 1} in
    newCounter =
      from the act of binding these methods to a particular set of instance variables:
      ⇐ counterClass : CounterRep → Counter
      inc = ∀-:Unit. x.x:=succ(! (x.x));
      get = ∀-:Unit. ! (x.x),
      xr:CounterRep.
      counterClass =
        the definition of the methods
        To avoid the problem we observed before, what we need to do is to separate

```

Classes

```
resetCounterClass =  $\lambda : CounterRep .$ 
 $\lambda x : CounterRep .$ 
    let super = CounterClass x in
        {get = super.get,
         inc = super.inc,
         reset =  $\lambda : Unit .$ 
                  $x := 1 \} ;$ 
    resetCounterRep =  $\lambda : CounterRep \rightarrow$ 
                     CounterClass : CounterRep  $\rightarrow$ 
                      $\lambda : Unit \rightarrow$  ResetCounter
newResetCounter =  $\lambda : Unit .$ 
                  let x = {x=xref 1} in
                  ResetCounterClass x;
```

Defining a Subclass

```
}

    void reset() { x = b; }

    void backup() { b = x; }

protected int b = 1;

class BackupCounter extends ResetCounter {
```

```
}

void reset() { x = 1; }

class ResetCounter extends Counter {
```

```
}

void inc() { x++; }

int get() { return x; }

protected int x = 1;

class Counter {
```

Overriding and adding instance variables

```

← backupCounterClass : BackupCounterRep ← BackupCounter

backup = ∀_Unit. r.b := !(r.x);
reset = ∀_Unit. r.x := !(r.b),
inc = super.inc,
{get = super.get,
let super = resetCounterClass x in
    ∀r:BackupCounterRep.
        BackupCounter =
            BackupCounterRep = {x: Ref Nat, b: Ref Nat};
            reset: Unit → Unit, backup: Unit → Unit;
            BackupCounter = {get: Unit → Nat, inc: Unit → Unit,
                variables to its representation.
In general, when we define a subclass we will want to add new instances

```

Adding instance variables

```
backup = A_.Unit. x.b:=!(x.x){};  
reset = A_.Unit. x.x:=!(x.b),  
inc = super.inc,  
{get = super.get,  
let super = resetCounterClass x in  
AxBBackupCounterRep.  
backupCounterClass =
```

- ◆ **subtyping** is essential here (in the definition of **super**)
- ◆ **new reset**) the definition of **counterClass**
- ◆ **backupCounterClass** both extends (with **backup**) and overrides (with a

Notes:

```
==> FunnyBackupCounterClass : BackupCounterRep -> BackupCounter
```

```
    backup = super.backup;
    reset = super.reset;
    inc = A_.Unit. (super.backup unit; super.inc unit),
    {get = super.get,
     Let super = BackupCounterClass x in
     A:BackupCounterRep.
FunnyBackupCounterClass =
```

Suppose (for the sake of the example) that we wanted every call to `inc` to first back up the current state. We can avoid copying the code for `backup` by making `inc` use the `backup` and `inc` methods from `super`.

Calling `super`

What if counters have `set`, `get`, and `inc` methods:

```
SetCounter = {get:Unit→Nat, set:Nat→Unit, inc:Unit→Unit};  
SetCounterClass =  
  Ax:CounterRep.  
    {get = Ax:Unit. i(x.x),  
     set = Ax:Nat. x.x:=i,  
     inc = Ax:Unit. x.x:=(succ x.x) {}};
```

Calling between methods

Can we rewrite this class so that the `get/set` functionality appears just once?

functionality of `get` and `set`.

Bad style: The functionality of `inc` could be expressed in terms of the

```
inc = λ:Unit. x.x:=(succ x.x) () ;
set = λi:Nat. x.x:=i,
{get = λ:Unit. i(x.x),
Ax:CounterRep.
setCounterClass =
```

`SetCounter` = {`get:Unit→Nat`, `set:Nat→Unit`, `inc:Unit→Unit`} ;
 What if counters have `set`, `get`, and `inc` methods:

Calling between methods

```
        }  
    }  
void inc () { this.set (this.get () + 1); }  
void set (int i) { x = i; }  
int get () { return x; }  
protected int x = 0;  
class SetCounter {
```

In Java we would write:

Calling between methods

This is just a definition of a group of mutually recursive functions.
type of the `fix` expression is `SetCounter → SetCounter`.
Check: the type of the inner λ -abstraction is `SetCounter → SetCounter`, so the

```
inc = λ : Unit. this.set (succ (this.get unit))};  
set = λ i : Nat. x.x := i;  
{get = λ : Unit. !(x.x),  
(@this : SetCounter.  
fix  
λr : CounterRep.  
setCounterClass =
```

Better...

So this does **not** model the behavior of **this** (or **this**) in real OO languages.

is “closed” — we “tie the knot” when we build the record.

```
inc = λ:Unit. this.set (succ (this.get unit));  
set = λi:Nat. x.x:=i,  
get = λ:Unit. !(x.x),  
(@this: SetCounter.  
fix  
λr:CounterRep.  
Note that the fixed point in setCounterClass =
```

Idea: move the application of `fix` from the class definition...

`setCounterClass =`

`Ax:CounterRep.`

`At this: SetCounter.`

`{get = Ax:Unit. ! (x.x),
set = Ai:Nat. x.x:=i,`

`inc = Ax:Unit. this.set (succ(this.get unit))};`

...to the object creation function:

`newSetCounter =`

`A_.Unit. Let x = {x=ref l} in
fix (setCounterClass r);`

In essence, we are switching the order of `fix` and `Ax:CounterRep...`

Note that we have changed the **types** of classes from... `SetCounterClass` =

fix

`Ar:CounterRep.`

`(At this: SetCounter.`

`{get = λ :Unit. ! (x.x),`

`set = λ i:Nat. x.x:=i,`

`inc = λ :Unit. this.set (succ (this.get unit))};`

`SetCounterClass : CounterRep \rightarrow SetCounter \rightarrow SetCounter`

`=> SetCounterClass : CounterRep \rightarrow SetCounter \rightarrow SetCounter`

Let's continue the example by defining a new class of counter objects (a subclass of set-counters) that keeps a record of the number of times the `set` method has ever been called.

```
InstrCounter = {get:Unit→Nat, set:Nat→Unit,  
inc:Unit→Unit, accesses:Unit→Nat};  
InstrCounterRep = {x: Ref Nat, a: Ref Nat};
```

Using this

- ◆ `super` plays a crucial role (twice) in the call to `setCounterClass`
- ◆ the `inc` in `super` will call the `set` defined here, which calls the superclass (which is constructed using `this` and the instance variables)
- ◆ the methods use both `this` (which is passed as a parameter) and `super`

Notes:

`InstructionCounter` : `InstructionCounterRep` \leftarrow `InstructionCounter` \leftarrow `InstructionCounter`

```

accesses =  $\lambda$ :Unit. !(r.a){};

inc = super.inc,
set =  $\lambda$ i:Nat. (r.a:=succ !(r.a)); super.set i),
get = super.get,
let super = setCounterClass r this in
   $\lambda$ this: InstructionCounter.
     $\lambda$ x:InstructionCounterRep.
      InstructionCounter =

```

One more refinement...

...

```
    let super = setCounterClass x this in
      this : InstrCounter.
      x : InstrCounterRep.
      InstrCounterClass =
this in the call to setCounterClass in InstrCounterClass:
Intuitively (see TAPL for details), the problem is the “unprotected” use of
will cause the evaluator to diverge!
fix (InstrCounterClass x);
A^-Unit. Let x = {x=ref l, a=ref 0} in
newInstrCounter =
because calling the object creation function
The implementation we have given for instrumented counters is not very useful
```

A small fly in the ointment

To see why this diverges, consider a simpler example:

$\text{ff} = \lambda f : \text{Nat} \rightarrow \text{Nat}. f$

$\text{Let } f' = f \text{ in }$

$\lambda n : \text{Nat}. 0$

$\Leftarrow \text{ff} : (\text{Nat} \rightarrow \text{Nat}) \rightarrow (\text{Nat} \rightarrow \text{Nat})$

Now:

$\text{fix ff} \quad \text{ff (fix ff)}$

$\text{Let } f' = (\text{fix ff}) \text{ in } \lambda n : \text{Nat}. 0$

$\Leftarrow \text{let } f' = \text{ff (fix ff)} \text{ in } \lambda n : \text{Nat}. 0$

uh oh...

```

Idea: “delay” this by putting a dummy abstraction in front of it...
setCounterClass =  $\lambda x: CounterRep .$ 
 $\lambda this: Unit \rightarrow SetCounter .$ 
 $\lambda inc = \lambda : Unit .$   $(this\ unit) . set(succ((this\ unit) . get\ unit)) ;$ 
 $\lambda set = \lambda i: Nat .$   $x . x := i ,$ 
 $\{get = \lambda : Unit . ! (x . x) ,$ 
 $\lambda : Unit .$ 
newSetCounter =  $\lambda : Unit .$  Let  $x = \{x = ref\ l\}$  in
fix (setCounterClass x) unit;

```

One possible solution

Similarly:

```

InstrumentCounterClass = 
    ThisUnit: Unit --> InstrumentCounter.
    Ax: InstrumentCounterRep.
    Let super = setCounterClass x this unit in
        Ax: Unit.
        {
            get = super.get,
            set = Ai:Nat. (x.a:=succ(i(x.a)); super.set i),
            inc = super.inc,
            accesses = Ax: Unit. !(r.a){};
        }
    newInstrumentCounter =
        Ax:Unit. Let x = {x=ref 1, a=ref 0} in
            fix (InstrumentCounterClass x) unit;

```

This works, in the sense that we can now instantiate `InstrumentCounterClass` (without diverging!), and its instances behave in the way we intended.

Success

This works, in the sense that we can now instantiate `InstrumentCounterClass` (without `delaying`), and its instances behave in the way we intended.

However, all the “delaying” we added has an unfortunate side effect: instead of

computing the “method table” just once, when an object is created, we will

now re-compute it every time we invoke a method!

Section 18.12 in TAPL shows how this can be repaired by using references instead of `fix` to “tie the knot” in the method table.

instead of `fix` to “tie the knot” in the method table.

Recap

Multiple representations

All the objects we have built in this series of examples have type `Counter`.

But their internal representations vary widely.

An object is a record of functions, which maintain common internal state via a shared reference to a record of mutable instance variables.
This state is inaccessible outside of the object because there is no way to name it. (Instance variables can only be named from inside the methods.)

Encapsulation

Subtyping between object types is just ordinary subtyping between types of records of functions.

Functions like `inc3` that expect `Counter` objects as parameters can (safely) be called with objects belonging to any subtype of `Counter`.

Subtyping

- Classes are data structures that can be both extended and instantiated.
- We modeled inheritance by copying implementations of methods from superclasses to subclasses.
- Each class
- ◆ waits to be told a record `x` of instance variables and an object `this` (which should have the same interface and be based on the same record of instance variables to instantiate its superclass)
 - ◆ uses `x` and `this` to instantiate its superclass
 - ◆ constructs a record of method implementations, copying some directly from `super` and implementing others in terms of `this` and `super`.
 - ◆ The `this` parameter is “resolved” at object creation time using `fix`.

Inheritance

[Not to be handed in — just for you to check your understanding.]

Take all the examples from this lecture (and the previous one), and record them in Java.

Additional exercise
