Fast Fourier Transform (FFT)

Penn ESE 531 Spring 2020 – Khanna

Fast Fourier Transform Algorithms

- We are interested in efficient computing methods for the DFT and inverse DFT:

$$X[k] = \sum_{n=0}^{N-1} x[n] W_N^{kn}, \quad k = 0, \dots, N-1$$
$$x[n] = \sum_{k=0}^{N-1} X[k] W_N^{-kn}, \quad n = 0, \dots, N-1$$

$$W_N = e^{-j\left(\frac{2\pi}{N}\right)}.$$

4

Reminder: Inverse DFT via DFT

- Recall that we can use the DFT to compute the inverse DFT:

$$\mathcal{DFT}^{-1}\{X[k]\} = \frac{1}{N} (\mathcal{DFT}\{X^*[k]\})^*$$

- Hence, we can just focus on efficient computation of the DFT.
- Straightforward computation of an N-point DFT (or inverse DFT) requires N^2 complex multiplications.

5

Computation Order

- Fast Fourier transform algorithms enable computation of an N-point DFT (or inverse DFT) with the order of just $N \cdot \log_2 N$ complex multiplications.
 - This can represent a huge reduction in computational load, especially for large N.

Eigenfunction Properties

- Most FFT algorithms exploit the following properties of W_N^{kn} :
 - Conjugate Symmetry

$$W_N^{k(N-n)} = W_N^{-kn} = (W_N^{kn})^*$$

- Periodicity in n and k

$$W_N^{kn} = W_N^{k(n+N)} = W_N^{(k+N)n}$$

- Power

$$W_N^2 = W_{N/2}$$

FFT Algorithms via Decimation

- Most FFT algorithms decompose the computation of a DFT into successively smaller DFT computations.
 - Decimation-in-time algorithms decompose $x[n]$ into successively smaller subsequences.
 - Decimation-in-frequency algorithms decompose $X[k]$ into successively smaller subsequences.
- Note: Assume length of $x[n]$ is power of 2 ($N = 2^L$). If not, zero-pad to closest power of 2.

Decimation-in-Time FFT

- We start with the DFT

$$X[k] = \sum_{n=0}^{N-1} x[n] W_N^{kn}, \quad k = 0, \dots, N-1$$

- Separate the sum into even and odd terms:

$$X[k] = \sum_{n \text{ even}} x[n] W_N^{kn} + \sum_{n \text{ odd}} x[n] W_N^{kn}$$

- At this point for the 8 sample DFT, we can replace the $N/4 = 2$ sample DFT's with a single butterfly. The fundamental eigenfunction is:

$$W_{N/4} = W_{8/4} = W_2 = e^{-j\pi} = -1$$

Non-Power-of-2 FFTs

- A similar argument applies for any length DFT, where the length N is a composite number

80

Non-Power-of-2 FFTs

- Good component DFTs are available for lengths up to 20(ish). Many of these exploit the structure for that specific length

- For example, a factor of

$$W_N^{N/4} = e^{-j\frac{2\pi}{N}(N/4)} = e^{-j\frac{\pi}{2}} = -j$$

Just swaps the real and imaginary components of a complex number. Hence a DFT of length 4 doesn't require any complex multiples.

- Half of the multiples of an 8-point DFT also don't require multiplication
- Composite length FFTs can be very efficient for any length that factors into terms of this order

Penn ESE 531 Spring 2020 - Khanna
Adapted from M. Lustig, EECS Berkeley

81

Non-Power-of-2 FFTs

- For example $N = 693$ factors into
 - $N = (7)(9)(11)$
- each of which can be implemented efficiently. We would perform
 - 9 x 11 DFTs of length 7
 - 7 x 11 DFTs of length 9, and
 - 7 x 9 DFTs of length 11

82

Non-Power-of-2 FFTs

- Historically, the power-of-two FFTs were much faster (better written and implemented).
- For non-power-of-two length, it was faster to zero pad to power of two.
- Recently this has changed. The free FFTW package implements very efficient algorithms for almost any filter length. [Matlab has used FFTW since version 6](#)

Big Ideas

- Fast Fourier Transform
 - Enable computation of an N -point DFT (or DFT^{-1}) with the order of just $N \cdot \log_2 N$ complex multiplications.
 - Most FFT algorithms decompose the computation of a DFT into successively smaller DFT computations.
 - Decimation-in-time algorithms
 - Decimation-in-frequency
 - Historically, power-of-2 DFTs had highest efficiency
 - Modern computing has led to non-power-of-2 FFTs with high efficiency
 - Sparsity leads to reduced computation on order $K \cdot \log N$
