Lecture 24: April 11, 2021

Fast Fourier Transform Pt 2

# Lecture Outline

---

- ❑ FFT practice
- ❑ Chirp Transform Algorithm
- ❑ Circular convolution as linear convolution with aliasing

# Example 1:

---

A long *periodic* sequence  $x$  of period  $N = 2^r$  ( $r$  is an integer) is to be convolved with a finite-length sequence  $h$  of length  $K$ .

(a) *Show* that the output  $y$  of this convolution (filtering) is *periodic*; what is its period?

# Example 1:

---

A long *periodic* sequence  $x$  of period  $N = 2^r$  ( $r$  is an integer) is to be convolved with a finite-length sequence  $h$  of length  $K$ .

- (a) *Show* that the output  $y$  of this convolution (filtering) is *periodic*; what is its period?
- (b) Let  $K = mN$  where  $m$  is an integer;  $N$  is large. How would you implement this convolution *efficiently*? Explain your analysis clearly.

Compare the *total number of multiplications* required in your scheme to that in the direct implementation of FIR filtering. (Consider the case  $r = 10$ ,  $m = 10$ ).

# Example 1:

A long *periodic* sequence  $x$  of period  $N = 2^r$  ( $r$  is an integer) is to be convolved with a finite-length sequence  $h$  of length  $K$ .

- (a) *Show* that the output  $y$  of this convolution (filtering) is *periodic*; what is its period?
- (b) Let  $K = mN$  where  $m$  is an integer;  $N$  is large. How would you implement this convolution *efficiently*? Explain your analysis clearly.

Compare the *total number of multiplications* required in your scheme to that in the direct implementation of FIR filtering. (Consider the case  $r = 10$ ,  $m = 10$ ).

## Example 2:

---

A sequence  $x = \{x[n], n = 0, 1, \dots, N-1\}$  is given; let  $X(e^{j\omega})$  be its DTFT.

- (a) Suppose  $N = 10$ . You want to evaluate both  $X(e^{j2\pi 7/12})$  and  $X(e^{j2\pi 3/8})$ . The only computation you can perform is one DFT, on any one input sequence of your choice. Can you find the desired DTFT values? (*Show your analysis and explain clearly.*)

## Example 2:

A sequence  $x = \{x[n], n = 0, 1, \dots, N-1\}$  is given; let  $X(e^{j\omega})$  be its DTFT.

(b) Suppose  $N$  is large. You want to obtain  $X(e^{j\omega})$  at the following  $2M$  frequencies:

$$\omega = \frac{2\pi}{M}m, \quad m = 0, 1, \dots, M-1 \quad \text{and} \quad \omega = \frac{2\pi}{M}m + \frac{2\pi}{N}, \quad m = 0, 1, \dots, M-1.$$

Here  $M = 2^\mu \ll N = 2^\nu$

A standard radix-2 FFT algorithm is available. You may execute the FFT algorithm *once or more than once*, and *multiplications* and *additions* outside of the FFT are *allowed*, if necessary.

- (i) You want to get the  $2M$  DTFT values with as few *total multiplications* as possible (*including those in the FFT*). Give explicitly the best method you can find for this, with an estimate of the *total number of multiplications* needed in terms of  $M$  and  $N$ .

## Example 2:

A sequence  $x = \{x[n], n = 0, 1, \dots, N-1\}$  is given; let  $X(e^{j\omega})$  be its DTFT.

(b) Suppose  $N$  is large. You want to obtain  $X(e^{j\omega})$  at the following  $2M$  frequencies:

$$\omega = \frac{2\pi}{M}m, \quad m = 0, 1, \dots, M-1 \quad \text{and} \quad \omega = \frac{2\pi}{M}m + \frac{2\pi}{N}, \quad m = 0, 1, \dots, M-1.$$

Here  $M = 2^\mu \ll N = 2^\nu$

A standard radix-2 FFT algorithm is available. You may execute the FFT algorithm *once or more than once*, and *multiplications* and *additions* outside of the FFT are *allowed*, if necessary.

- (i) You want to get the  $2M$  DTFT values with as few *total multiplications* as possible (*including those in the FFT*). Give explicitly the best method you can find for this, with an estimate of the *total number of multiplications* needed in terms of  $M$  and  $N$ .
- (ii) Does your result change if extra multiplications outside of FFTs are *not* allowed?

# Chirp Transfer Algorithm

---

# Chirp Transform Algorithm

---

- ❑ Uses convolution to evaluate the DFT
- ❑ This algorithm is not optimal in minimizing any measure of computational complexity, but it has been useful in a variety of applications, particularly when implemented in technologies that are well suited to doing convolution with a fixed, pre-specified impulse response.
- ❑ The CTA is also more flexible than the FFT, since it can be used to compute *any* set of equally spaced samples of the Fourier transform on the unit circle.

# Chirp Transform Algorithm

For  $M$  points of DTFT  
uniformly spaced on a  
sector of unit-circle

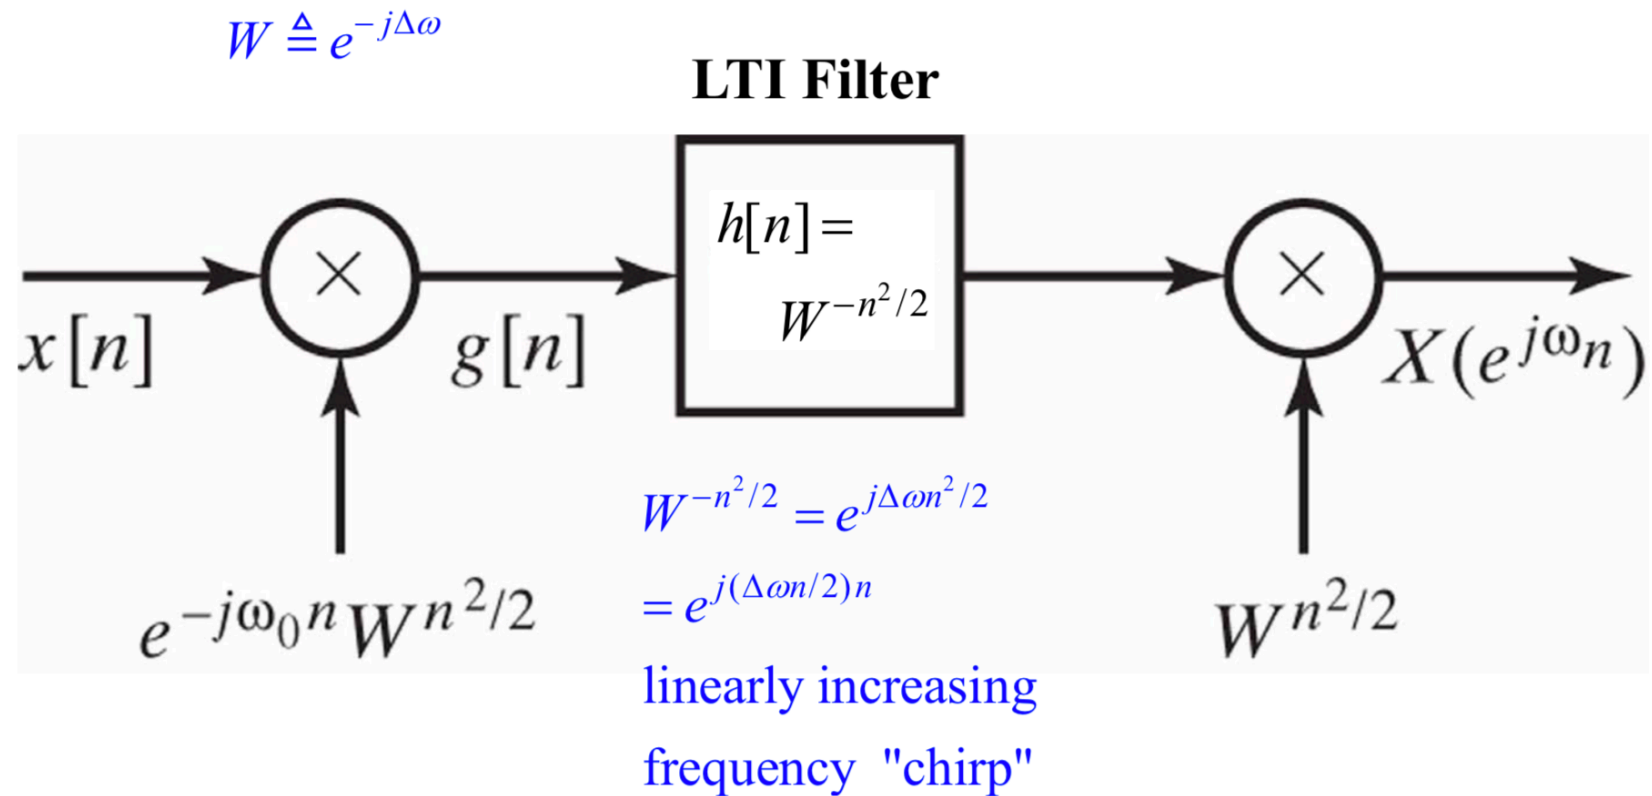

# Chirp Transform Algorithm

For  $M$  points of DTFT  
uniformly spaced on a  
sector of unit-circle

When  $\omega_0=0$  and  $M=N$ ,  
we just get the DFT

# Chirp Transform Algorithm

# Causal FIR CTA

$$h_1[n] = \begin{cases} W^{-(n-N+1)^2/2}, & n = 0, 1, \dots, M + N - 2, \\ 0, & \text{otherwise.} \end{cases}$$

$$X(e^{j\omega_n}) = y_1[n + N - 1], \quad n = 0, 1, \dots, M - 1.$$

# Example: Chirp Transform Parameters

- We have a finite-length sequence  $x[n]$  that is nonzero only on the interval  $n = 0, \dots, 25$ , (Length  $N=26$ ) and we wish to compute 16 samples of the DTFT  $X(e^{j\omega})$  at the frequencies  $\omega_k = 2\pi/27 + 2\pi k/1024$  for  $k = 0, \dots, 15$ .

For  $M$  points of DTFT  
uniformly spaced on a  
sector of unit-circle

# Circular Convolution

---

Linear Convolution with aliasing!

# Circular Convolution

□ Circular Convolution:

$$x_1[n] \circledN x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n - m))_N]$$

For two signals of length  $N$

**Note: Circular convolution is commutative**

$$x_2[n] \circledN x_1[n] = x_1[n] \circledN x_2[n]$$

# Compute Circular Convolution Sum

$$x_1[n] \circledcirc x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n - m))_N]$$

# Compute Circular Convolution Sum

$$x_1[n] \circledcirc x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n - m))_N]$$

# Compute Circular Convolution Sum

$$x_1[n] \circledcirc x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n - m))_N]$$

# Compute Circular Convolution Sum

$$y[0]=2$$

$$x_1[n] \circledast x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n-m))_N]$$

# Compute Circular Convolution Sum

$$y[0]=2$$

$$y[1]=2$$

$$x_1[n] \circledast x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n - m))_N]$$

# Compute Circular Convolution Sum

$$\begin{aligned} y[0] &= 2 \\ y[1] &= 2 \\ y[2] &= 3 \end{aligned}$$

$$x_1[n] \circledast x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n - m))_N]$$

# Compute Circular Convolution Sum

$$x_1[n] \circledast x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n-m))_N]$$

# Result

$y[0]=2$   
 $y[1]=2$   
 $y[2]=3$   
 $y[3]=4$

$$x_1[n] \circledN x_2[n] \triangleq \sum_{m=0}^{N-1} x_1[m] x_2[((n-m))_N]$$

# Linear Convolution

---

- We start with two non-periodic sequences:

$$x[n] \quad 0 \leq n \leq L - 1$$

$$h[n] \quad 0 \leq n \leq P - 1$$

- E.g.  $x[n]$  is a signal and  $h[n]$  a filter's impulse response

- We want to compute the linear convolution:

$$y[n] = x[n] * h[n] = \sum_{m=0}^{L-1} x[m]h[n-m]$$

- $y[n]$  is nonzero for  $0 \leq n \leq L+P-2$  with length  $M=L+P-1$

Requires  $LP$  multiplications

# Linear Convolution via Circular Convolution

- ❑ Zero-pad  $x[n]$  by  $P-1$  zeros

$$x_{zp}[n] = \begin{cases} x[n] & 0 \leq n \leq L-1 \\ 0 & L \leq n \leq L+P-2 \end{cases}$$

- ❑ Zero-pad  $h[n]$  by  $L-1$  zeros

$$h_{zp}[n] = \begin{cases} h[n] & 0 \leq n \leq P-1 \\ 0 & P \leq n \leq L+P-2 \end{cases}$$

- ❑ Now, both sequences are length  $M=L+P-1$

## Circular Conv. via Linear Conv. w/ Aliasing

- If the DTFT  $X(e^{j\omega})$  of a sequence  $x[n]$  is sampled at  $N$  frequencies  $\omega_k = 2\pi k/N$ , then the resulting sequence  $X[k]$  corresponds to the periodic sequence

$$\tilde{x}[n] = \sum_{r=-\infty}^{\infty} x[n - rN].$$

- And  $X[k] = \begin{cases} X(e^{j(2\pi k/N)}), & 0 \leq k \leq N-1, \\ 0, & \text{otherwise,} \end{cases}$  is the DFT of one period given as

$$x_p[n] = \begin{cases} \tilde{x}[n], & 0 \leq n \leq N-1, \\ 0, & \text{otherwise.} \end{cases}$$

## Circular Conv. via Linear Conv. w/ Aliasing

---

$$x_p[n] = \begin{cases} \tilde{x}[n], & 0 \leq n \leq N-1, \\ 0, & \text{otherwise.} \end{cases}$$

- ❑ If  $x[n]$  has length less than or equal to  $N$ , then  $x_p[n] = x[n]$
- ❑ However if the length of  $x[n]$  is greater than  $N$ , this might not be true and we get aliasing in time
  - $N$ -point convolution results in  $N$ -point sequence

## Circular Conv. via Linear Conv. w/ Aliasing

---

- Given two N-point sequences ( $x_1[n]$  and  $x_2[n]$ ) and their N-point DFTs ( $X_1[k]$  and  $X_2[k]$ )
- The N-point DFT of  $x_3[n]=x_1[n]*x_2[n]$  is defined as

$$X_3[k] = X_3(e^{j(2\pi k/N)})$$

## Circular Conv. via Linear Conv. w/ Aliasing

- Given two N-point sequences ( $x_1[n]$  and  $x_2[n]$ ) and their N-point DFTs ( $X_1[k]$  and  $X_2[k]$ )
- The N-point DFT of  $x_3[n]=x_1[n]*x_2[n]$  is defined as

$$X_3[k] = X_3(e^{j(2\pi k/N)})$$

- And  $X_3[k]=X_1[k]X_2[k]$ , where the inverse DFT of  $X_3[k]$  is

$$x_{3p}[n] = \begin{cases} \sum_{r=-\infty}^{\infty} x_3[n - rN], & 0 \leq n \leq N - 1, \\ 0, & \text{otherwise,} \end{cases}$$

# Circular Conv. as Linear Conv. w/ Aliasing

---

$$x_{3p}[n] = \begin{cases} \sum_{r=-\infty}^{\infty} x_3[n - rN], & 0 \leq n \leq N - 1, \\ 0, & \text{otherwise,} \end{cases}$$

# Circular Conv. as Linear Conv. w/ Aliasing

$$x_{3p}[n] = \begin{cases} \sum_{r=-\infty}^{\infty} x_3[n - rN], & 0 \leq n \leq N - 1, \\ 0, & \text{otherwise,} \end{cases}$$

□ Thus

$$x_{3p}[n] = \begin{cases} \sum_{r=-\infty}^{\infty} x_1[n - rN] * x_2[n - rN] & 0 \leq n \leq N - 1 \\ 0 & \text{else} \end{cases}$$
$$x_{3p}[n] = x_1[n] \circledast x_2[n]$$

- The N-point circular convolution is the sum of linear convolutions shifted in time by N

## Example 1:

---

□ Let

□ The  $N=L=6$ -point circular convolution results in

# Example 1:

□ Let

□ The  $N=L=6$ -point circular convolution results in

## Example 1:

## Example 2:

- The L-shifted linear convolutions

# Big Ideas

---

- ❑ Discrete Fourier Transform (DFT)
  - For finite signals assumed to be zero outside of defined length
  - N-point DFT is sampled DTFT at N points
  - Useful properties allow easier linear convolution
- ❑ Fast Fourier Transform
  - Enable computation of an N-point DFT (or  $\text{DFT}^{-1}$ ) with the order of just  $N \cdot \log_2 N$  complex multiplications.
- ❑ Fast Convolution Methods
  - Use circular convolution (i.e DFT) to perform fast linear convolution
    - Overlap-Add, Overlap-Save
  - Circular convolution is linear convolution with aliasing
- ❑ Design DSP methods to minimize computations!
