Trigonometric Identity:

$$e^{j\Theta} = cos(\Theta) + jsin(\Theta)$$

Geometric Series:

$$\sum_{n=0}^{N} r^n = \frac{1-r^{N+1}}{1-r}$$
$$\sum_{n=0}^{\infty} r^n = \frac{1}{1-r}, |r| < 1$$

DTFT Equations:

$$X(e^{j\omega}) = \sum_{k=-\infty}^{\infty} x[k]e^{-j\omega k}$$
$$x[n] = \frac{1}{2\pi}\int_{-\pi}^{\pi} X(e^{j\omega})e^{j\omega n}d\omega$$

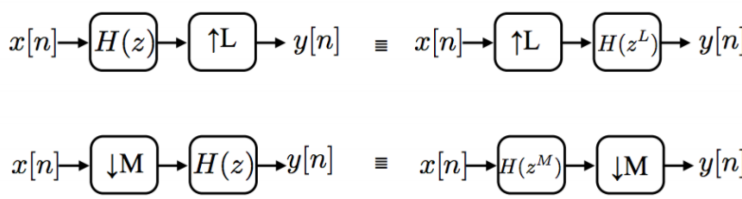
$$x[n] = \frac{1}{2\pi j} \oint_C X(z) z^{n-1} dz$$

Upsampling/Downsampling:

Upsampling by L (↑L): $X_{up} = X(e^{j\omega L})$

Downsampling by M (↓M): $X_{down} = \frac{1}{M} \sum_{i=0}^{M-1} X(e^{j(\frac{\omega}{M} - \frac{2\pi}{M} i)})$

Interchange Identities:



1. (20 points) Consider the system shown in Figure 1 for discrete-time processing of the continuous-time input signal $g_c(t)$. The input signal $g_c(t)$ is of the form $g_c(t) = f_c(t) + e_c(t)$. where the Fourier transforms of $f_c(t)$ and $e_c(t)$ are shown in Figure 2. Since the input signal is not bandlimited, a continuous-time antialiasing filter $H_{aa}(j\Omega)$ is used. The frequency response for $H_{aa}(j\Omega)$ is shown in Figure 3. Assume the C/D and D/C blocks are ideal as in class. Ideal means that the D/C converter contains an ideal lowpass reconstruction filter with a bandwidth of π/T and a gain of T.

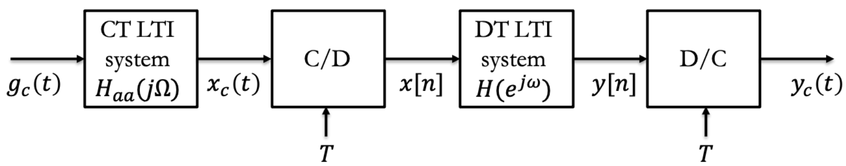


Figure 1

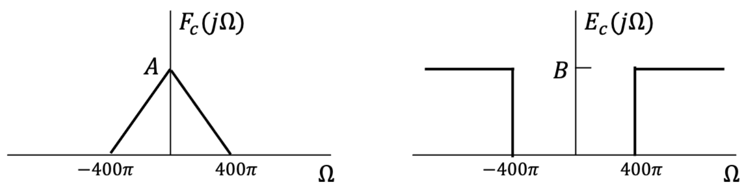

Figure 2

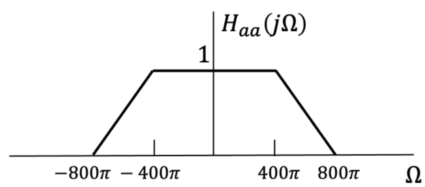

Figure 3

(a) If the sampling rate is $\Omega_S = 1600\pi$, determine $H(e^{j\omega})$, the frequency response of the discrete-time system, so that the output is $y_c(t) = f_c(t)$.

(b) It turns out that since we are only interested in obtaining $f_c(t)$ at the output, we can use a lower sampling rate than $\Omega_S = 1600\pi$ while still using the antialiasing filter in Figure 3. Determine the minimum value of Ω_S such that $y_c(t) = f_c(t)$? Determine $H(e^{j\omega})$ for this new choice of Ω_S.

2. (30 points) The discrete-time filtering system shown in Figure 4 comprises a C/D converter sampling at rate $f_1 = 2000Hz$, a filter with frequency response $H(e^{j\omega})$, a resampler that resamples at a rate of $D : U$ (downsample by D, and upsample by U) and an ideal D/C converter at rate f_2. Ideal means that the D/C converter contains an ideal lowpass reconstruction filter with a bandwidth of πf_2 and a gain of $1/f_2$. The spectrum of the input, $X(j\Omega)$, and frequency response, $H(e^{j\omega})$, are shown in Figure 5.

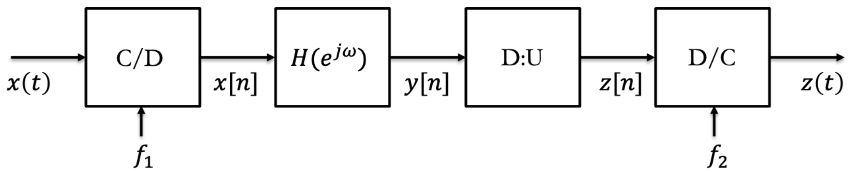

Figure 4

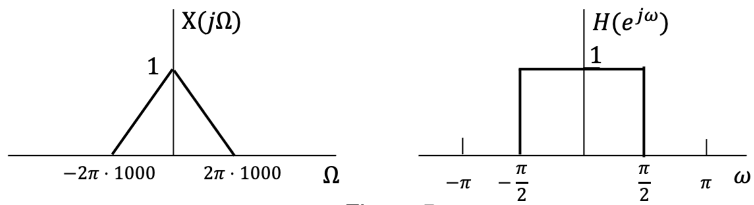

Figure 5

(a) Plot the spectra $X(e^{j\omega})$ and $Y(e^{j\omega})$. Label all axes and relevant features.

(b) Given $f_2 = 1000Hz$, $U = 1$, and $D = 2$, plot the spectra $Z(e^{j\omega})$ and $Z(j\Omega)$. Label all axes and relevant features.

(c) Given $f_2 = 4000Hz$, $U = 2$, and $D = 1$, plot the spectra $Z(e^{j\omega})$ and $Z(j\Omega)$. Label all axes and relevant features.

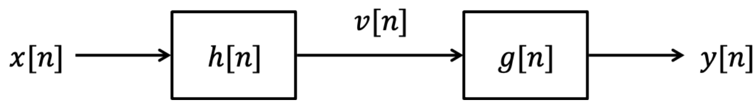
3. (30 points) A stable system is shown below, comprising a cascade of two LTI discrete-time filters such that $y[n] = x[n]$.



The first filter has an unknown impulse response, $h[n]$. The second filter is defined by the difference equation:

$$y[n] = v[n] - \frac{3}{4}v[n-1] + \frac{1}{8}v[n-2] \tag{1}$$

For each filter $G(z)$ and $H(z)$ in the combined system:

(a) Find the transfer function and impulse response.

(b) Plot the filter pole-zero plot and indicate the ROC.

(c) Indicate if the filter is all-pass, min-phase, or neither. Explain your reasoning.

4. (20 points) For each $H(z)$ in the table below, select the matching magnitude response from the magnitude plots M1-M6 also shown below. It is possible that some pictures may apply to more than one system, and some pictures will not apply to any system. If none of the pictures is possible, write none.
