A Brief Introduction to Program Verification and Constraint Solving
In this paper an attempt is made to explore the logical foundations of computer programming by use of techniques which were first applied in the study of geometry and have later been extended to other branches of mathematics. This involves the elucidation of sets of axioms and rules of inference which can be used in proofs of the properties of computer programs. Examples are given of such axioms and rules, and a formal proof of a simple theorem is displayed. Finally, it is argued that important advantage, both theoretical and practical, may follow from a pursuance of these topics.
Architects draw detailed plans before a brick is laid or a nail is hammered. But few programmers write even a rough sketch of what their programs will do before they start coding. We can learn from architects. A blueprint for a program is called a specification. An architect's blueprint is a useful metaphor for a software specification.

The need for specifications follows from two observations. The first is that it is a good idea to think about what we are going to do before doing it, and as the cartoonist Guindon wrote: "Writing is nature's way of letting you know how sloppy your thinking is." The second observation is that to write a good program, we need to think above the code level.

The main reason for writing a formal spec is to apply tools to check it. Tools cannot find design errors in informal specifications.
Specifications for programs

Input: int x, int y
Output: int r

\[
z := x + y;
z' := x - y;
r := z * z'
\]

Post-condition / assertion / “ensures” (in Dafny): \[ r = x^2 - y^2 \]

Cannot define correctness without specifications (logical constraints)
Verification Conditions

Input: int x, int y
Output: int r

\[ z := x + y; \]
\[ z' := x - y; \]
\[ r := z \times z' \]

Ensures \( r = x^2 - y^2 \)

Verifying correctness means checking validity of the following logical formula, called VC (Verification Condition):

\[( z = x+y \land z' = x-y \land r = z\times z' ) \Rightarrow r = x^2 - y^2 \]
Verification problem: check validity of

\[( z = x+y \text{ \&\& } z' = x-y \text{ \&\& } r = z\times z' ) \Rightarrow r = x^2 - y^2 \]

The answer is NO if the following set of constraints over integer variables are satisfiable:

\{ z = x+y; z' = x-y; \quad r = z\times z'; r \neq x^2 - y^2 \}

Satisfying solution to these constraints is a “counterexample” or a bug that shows why the program is incorrect
Example Constraint Satisfaction Problem

$x, y, z$ : Boolean variables
Find values such that all the following constraints are satisfied

$x \mid \neg y \mid \neg z$
$\neg x \mid y \mid \neg z$
$\neg x \mid \neg y \mid z$
Example Constraint Satisfaction Problem

\(x, y, z: \text{ real-valued variables}\)

Find values such that all the following constraints are satisfied

\[
\begin{align*}
2x + 3y - 5z & \leq 7 \\
-5x + 2y & \leq 106 \\
9x - 4y + 29z & \leq -1
\end{align*}
\]

What if we change the type to “integer” variables
Example Constraint Satisfaction Problem

\[ x, y, z : \text{real-valued variables} \]
Find values such that all the following constraints are satisfied

\[ 2x + 3y - 5z \leq 7 \quad | \quad 3x - 4z \leq 9 \]
\[ -5x + 2y \leq 106 \quad | \quad 6y - 78z \leq 567 \]
\[ 9x - 4y + 29z \leq -1 \quad | \quad 5x - 7y + z \leq 98 \]

Mixture of Boolean and linear constraints
Solving Sudoku As Constraint Satisfaction
Solving Sudoku As Constraint Satisfaction

Variables: \(x(i,j)\), for \(i=1..9\) and \(j=1..9\), of integer value between 1 and 9
Find values such that all the following constraints are satisfied

Some values are known:
\[x(3,3)=1, \, x(2,6)=3, \, \ldots\]
Every value appears in each row:
for each \(k=1, \ldots, 9\):
for each \(i=1, \ldots, 9\):
\[x(i,1)=k \mid x(i,2)=k \mid \ldots \mid x(i,9)=k\]
Every value appears in each column: similar constraints
Every value appears in each square:
for each \(k=1, \ldots, 9\),
\[x(1,1)=k \mid x(1,2)=k \mid x(1,3)=k \mid \ldots \mid x(3,2)=k \mid x(3,3)=k\]
A Verification Example

Input: int[32] x, y /* fixed precision 32 bit integers (as in C) */
Output: int[32] r

int[32] z := x + y; /* what's the precise semantics of addition?? */
r := z / 2

Ensures (x + y = 2r) /* r is average of x and y */

Verification condition: Validity over int[32] variables

z = x + y && r = z/2 \Rightarrow (x + y = 2r)

Constraint satisfaction problem:

\{ z = x + y; r = z/2; x + y \neq 2r \}

Satisfying solution: x=y=2^{32} - 1; r=z=0

Types matter!
Need to capture precise semantics of language constructs!
Logic for Specifications

Specification is a logical formula constructed from expressions over program variables using logical operators AND &&, OR |, NOT ~
Different choices based on:

- **Allowed types of variables:**
  - Boolean (bool), integer (int), natural numbers (nat), real numbers (real)
  - Enumerated types
  - Bit-vectors (fixed precision integers): int[32], int[64]
  - Arrays and matrices

- **Operators allowed in expressions, e.g. for integers, three classes:**
  - Difference constraints: \( x - y \leq 5 \)
  - Linear constraints: \( 2x + 3y - 5z \leq 7 \)
  - Full arithmetic: \( r = x^2 - y^2 \)

- **Whether quantifiers over variables are allowed**

The more restricted the specification logic, easier it is for a tool to solve the resulting constraint satisfaction problem.
Verifying Programs with Loops

Input: int \(x_1, x_2\)
Output: int \(y_1, y_2\)

Requires \((0 \leq x_1 && x_2 > 0)\) /* Assumption on inputs; also called pre-condition */
y1 := 0;
y2 := x1;
while \((x_2 \leq y_2)\) {
y1 := y1+1;
y2 := y2 - x2
}
Ensures \((y_1 = x_1 \text{ div } x_2 && y_2 = x_1 \text{ rem } x_2)\)
Division Example

Current verification tools require the programmer also to specify “loop invariants”
Condition over program variables that is satisfied at the beginning of each iteration

Requires \((0 \leq x1 && x2 > 0)\)
\begin{align*}
y1 &:= 0; \\
y2 &:= x1; \\
\text{while } (x2 \leq y2) \{ \\
\text{Invariant } \phi : (x1 = y1 \times x2 + y2 && 0 \leq x1 && x2 > 0) \\
\quad y1 := y1+1; \\
\quad y2 := y2 - x2 \\
\}\; \\
\text{Ensures } (y1 = x1 \div x2 && y2 = x1 \bmod x2)
\end{align*}
Division Example

Requires \((0 \leq x1 \&\& x2 > 0)\)
\[y1 := 0;\]
\[y2 := x1;\]
\[\text{while } (x2 \leq y2) \{ \text{Invariant } \phi : (x1 = y1 \cdot x2 + y2 \&\& 0 \leq x1 \&\& x2 > 0)\]
\[y1 := y1+1;\]
\[y2 := y2 - x2\]
\};
\[\text{Ensures } (y1 = x1 \div x2 \&\& y2 = x1 \mod x2 )\]

Verification conditions:
1. Initialization ensures that invariant holds on first iteration
\((0 \leq x1 \&\& x2 > 0) \Rightarrow \phi[y1/0; y2/x1]\)
2. Execution of the loops preserves loop invariant
\((x2 \leq y2) \&\& \phi \Rightarrow \phi[y1/y1+1; y2/y2-x2]\)
3. Post-condition holds upon termination of loop
\(~(x2 \leq y2) \&\& \phi \Rightarrow (y1 = x1 \div x2 \&\& y2 = x1 \mod x2 )\)
Propositional Satisfiability: Given a formula over Boolean variables, is there an assignment of 0/1’s to variables which makes the formula true

- Canonical NP-hard problem (Cook 1973)
- Enormous progress in tools that can solve instances with thousands of variables and millions of clauses
- Also at the core of SMT solvers (extensions to richer classes of constraints)
Computational problem: Find a satisfying assignment to a formula
- Boolean + Int types, logical connectives, arithmetic operators
- Bit-vectors + bit-manipulation operations in C
- Boolean + Int types, logical/arithmetic ops + Uninterpreted functions

"Modulo Theory": Interpretation for symbols is fixed
- Can use specialized algorithms (e.g. for arithmetic constraints)

Progress in improved SMT solvers

Little Engines of Proof
SAT; Linear arithmetic; Congruence closure
SMT Solvers

Ever-growing scalability and use in different applications
Summary of Program Verification

- Proving correctness of programs requires programmer to write logical specifications
  - Pre/Post conditions for each function
  - Invariants for loops

- Proving correctness can then be translated automatically to constraint solving
  - Scalable SAT solvers for constraints over Boolean variable
  - Specialized scalable SMT solvers for more general classes of constraints / variable types

- Useful references
  - Satisfiability modulo theories: introduction and applications; de Moura and Bjorner; CACM 2011
  - The dogged pursuit of bug-free C programs: The Frama-C software analysis platform; Baudin et al; CACM, 2021

Use program verification tools to ensure correctness of code generated by LLMs

Active research area in programming systems / software engineering
Formal Verification of Neural Networks
What is a deep neural network?
Each layer is a function

\[(x_3, x_4) \leftarrow f_1(x_1, x_2) \text{ where} \]
\[x_3 = w_{13} \cdot x_1 + w_{23} \cdot x_2 + b_3 \]
\[x_4 = w_{14} \cdot x_1 + w_{24} \cdot x_2 + b_4 \]

\[(x_5, x_6) \leftarrow f_2(x_3, x_4) \text{ where} \]
\[x_5 = \text{ReLU}(x_3) = \max(0, x_3) \]
\[x_6 = \text{ReLU}(x_4) = \max(0, x_4) \]
DNN is composition of layerwise functions

\[(x_7, x_8) \leftarrow f(x_1, x_2) = f_3 \circ f_2 \circ f_1(x_1, x_2)\] where \(f_3\) is the function computed by the third layer
DNNs and Programs

- DNNs can be seen as straight-line programs (programs without loops)

\[
\begin{align*}
\text{def } f(x_1, x_2): \\
&x_3 = w_{13} \cdot x_1 + w_{23} \cdot x_2 + b_3 \\
&x_4 = w_{14} \cdot x_1 + w_{24} \cdot x_2 + b_4 \\
&x_5 = \max(0, x_3) \\
&x_6 = \max(0, x_4) \\
&x_7 = w_{57} \cdot x_5 + w_{67} \cdot x_6 + b_7 \\
&x_8 = w_{56} \cdot x_5 + w_{68} \cdot x_6 + b_8 \\
\text{return } x_7, x_8
\end{align*}
\]
Specifications over DNNs

Precondition

\[ \forall x_1, x_2, l_1 \leq x_1 \leq u_1, l_2 \leq x_2 \leq u_2 \]

DNN \( f \)

\[
\text{def } f(x_1, x_2):
\begin{align*}
  x_3 &= w_{13} \cdot x_1 + w_{23} \cdot x_2 + b_3 \\
  x_4 &= w_{14} \cdot x_1 + w_{24} \cdot x_2 + b_4 \\
  x_5 &= \max(0, x_3) \\
  x_6 &= \max(0, x_4) \\
  x_7 &= w_{57} \cdot x_5 + w_{67} \cdot x_6 + b_7 \\
  x_8 &= w_{56} \cdot x_5 + w_{68} \cdot x_6 + b_8 \\
\end{align*}
\]

\[ \text{return } x_7, x_8 \]

Postcondition

\[ x_7 > x_8 \]

Either prove that the network output satisfies the postcondition for all inputs in the pre-condition or find a counterexample.
Neural network certification: problem statement

Precondition over network inputs $\phi$

Network $f$

Postcondition over network outputs $\psi$
Neural network certification: problem statement

Precondition over network inputs $\phi$

Network $f$

Prove $f(\phi) \subseteq \psi$
Neural network certification: problem statement

Precondition over network inputs $\phi$

Find a counter example $i \in \phi$

Network $f$

$f(i)$ does not satisfy $\psi$

$f(\phi) \notin \psi$
Robustness against adversarial perturbations

Network correctly classifies $I_0$ as “car”.

$L_\infty$-ball around $I_0$ of radius $\epsilon$.

$0.6 \leq x_0 \leq 0.65$

$0.55 \leq x_1 \leq 0.6$

$\phi$ with $\epsilon = 8/255$

$\psi$: network classifies image as “car”
The general problem is computationally intractable, therefore we may need to provide an approximate answer.
Soundness and Completeness for Certification

<table>
<thead>
<tr>
<th>Sound</th>
<th>Complete</th>
<th>Guarantees</th>
